The Sacks et al. (1974) analysis of turn taking in ordinary conversation described arguably the most important organizing principles of face-to-face interaction – how participants in an interaction accomplish and coordinate the exchange of turns at talk. Many researchers consider the turn-taking system of ordinary conversation a basic set of organizing procedures which are then adjusted to form all of the other types of interactions. Adjacency pairs are two turn sequences (such as questions and answers or invitations and their acceptance or rejection) which enable participants to influence actions beyond their own turn and which can be combined in a variety of ways to produce more complex actions. In addition, routine mechanisms for “repair” of problems in talk are available to participants (Jefferson 1974), enabling them to restore mutual understanding and coordination of talk when it has broken down.

Conversation analytic studies are almost always based on naturally occurring interactions because the goal is to study what people actually do rather than artificial reconstructions or simulations of interaction. Conversation analysis involves the detailed analysis of audio or video recordings which are transcribed using a unique system developed by Gail Jefferson (1984). This transcription system preserves the details of the talk and how it was produced (including timing, simultaneous speech, repetitions, intonation, volume, and idiosyncratic pronunciations, among other characteristics). Heritage (1987) notes that social action works not *in spite of* but *because of* its details. Nonverbal behaviors, such as facial expressions and gaze direction, and the use of

settings and artifacts (e.g., documents, tools, or technology), are also critical components of human action. Conversation analysts take these behaviors into account, either using a system for transcribing such behaviors onto the transcript or viewing the videotape and noting such behaviors as relevant for the analysis.

Conversation analysts believe that discoveries can be best made by direct observation of social action rather than through a priori theory development and hypothesis testing. Sacks' (1984) argument is that as scientists, we are limited in terms of what we can hypothesize by what we can imagine. However, social life is much more complex than we could imagine, so a deductive hypothesis-generation approach will not effectively lead us toward knowledge about how participants construct their actions in everyday life. Instead, we use direct observation as a basis for theorizing (Heritage 1987). By observing human behavior directly, we can develop accurate theories about how people coordinate their actions and create intersubjective understanding.

Social scientific research that relies on a positivist approach uses theory building and testing via a deductive process involving the creation of hypotheses about the social world. Typically, statistical techniques are used to test hypotheses; these techniques rely on systematically derived samples from the population of interest. However, conversation analysts are not making statistical arguments about the relationships between variables they are studying actual behavior. Whether and how a given action is related to a subsequent action depends on its use in the local context and is visible through direct observation of the interaction itself and of participants' responses to that action. Because of this, the data sets used in conversation analytic research are described as "collections" rather than samples.

Conversation analysts collect examples of, observe closely, and attempt to categorize or describe conversational events in a way that makes their social organization (the procedures used to create them) visible. For example, Schegloff's (1979) paper on telephone call openings is generally held up as an example of an ideal

approach to the analysis of collections of data. He collected about 500 examples of telephone call openings. At first glance, the called party's "hello" when they pick up the phone looks like the beginning of the conversation, and it also looks like a greeting. But Schegloff noticed that the called person's "hello" lets the caller know that they have the phone at their ear and are now available for interaction. This "hello" is therefore the *second* turn in the interaction, not the first, and is an answer to the summons (the ringing of the phone), rather than a greeting. Schegloff was able to discover this phenomenon by observing a "deviant case" in which the phone rang and someone picked it up but did not speak. After a brief pause, the caller (instead of the person called) said "hello" in an attempt to elicit a response from the called party. Schegloff (1979) concluded that if the called person does not speak, the caller can speak first and use their turn at talk to repair the absence of the called party's response. What is important here is that Schegloff was not making a statistical argument (e.g., in 499 out of 500 calls, the called person speaks first), but an analytical argument which incorporated all 500 excerpts, even the so-called deviant case. The deviant case in which the caller spoke first still displayed an orientation to the rule that the called party *should* speak first. Conversation analysts also sometimes use the single case method. Single case analysis involves applying current conversation analytic knowledge to the understanding and explication of a single instance of interaction, often one which is problematic in nature. A single case analysis can be an effective diagnostic technique to discover the source of communication problems in specific situations, to find ways of avoiding or repairing these types of problems. For example, Whalen et al. (1988) analyze an emergency call to the police in which the caller became embroiled in an argument with the call taker which prevented them from successfully completing the business of the call (sending an ambulance).

In sum, while ethnomethodology and conversation analysis are very different from traditional sociology, they are profoundly sociological in their purpose and the subject matter of their

research. The extensive use of conversation analytic methods to study talk in workplace interactions and other organizational and professional settings has produced research with direct applicability to the improvement of the work done in those settings (see Heritage and Clayman 2010 for examples).

[Religious affiliation](#); [Religious commitment](#)

Description

Conversion is surely one the most intriguing and controversial issues in social sciences and humanities still resisting universal definition or theory. Already in 1908, George Jackson had clearly stated that conversion resists all “standardization” (Snow-Machalek 1984). Eighty years later, Thomas Robbins noted exactly the same by saying that conversion studies consist “of multiple confusions related to divergent premises, conceptual frameworks, nomenclature and behavioural referents have employed by researchers” (Robbins 1988). The current situation is not much different as there are no systematic programs of methodologically sophisticated research on conversion (Hood et al. 2009). One could say that conversion is simply a religious change, but in what sense religious, and what is the subject of the change? Conversion studies have no disciplinary autonomy. Conversion studies are represented by a bundle of various methods and approaches grouped under ambivalent concept of conversion depending on authors’ varied philosophical and theoretical affiliations and concerns. We, scholars of religion, need to pay attention to what way we conceptualize conversion into assumptions we adopt

and methods we use and in what ways our theories reflect our own intuition cultural pattern, and sociopolitical intention. As the term conversion is not a universal concept, it is hard to expect a theory free from the term's own history, cultural origins, and usages in particular religious and sociocultural contexts. Also as an analytic tool, conversion is often hardly useful in empirical research. Scholars engage conversion solely in a retrospective manner, and theories and models are often based on converts' first-hand reports.

Changing the Conversion Concept

The Latin word "convertere" (to revolve, turn around) connected with Greek words "strephe" and "epistrephe" or "metanoia" from the New Testament, refers to a positive state or process of committing oneself to new community, beliefs, and rituals in Judeo-Christian context (Flinn 1999). In the European Middle Ages, conversion was predominantly related to the religious intensification of one's piety and religiousness in a context of a monastic life, or to conversion of Jews and Muslims to Christianity. After the spread of Protestantism and distortion of medieval Church universality, conversion gained more individual character and became associated with a self-authenticating, intense, "newborn" experience guaranteeing personal and collective religious revival leading to a switch to a Christian denomination and distinguishing one as a "real Christian." Classical conversion forms of Christian Protestant life fully emerged after European Christian denominations flourished in American colonies, emphasizing a personal experience of God's saving grace. In spite of many ways of using this term in various Christian streams, conversion as a sudden and dramatic religious change leading the individual to a Christian community of believers has been preserved. Constructing conversion in religious studies is primarily a Christian, or more precisely, Protestant heritage. It was only later that conversion was discovered in religions under the disputable label of "world religions," like Buddhism or Islam. What was previously held about Christianity as unique and dramatically different from others

was now held as a category of religion and religious experience. This is most apparent in early psychological conversion studies, but also present in conversion studies in general.

Early Psychological Conversion Studies

The first scientific psychology paper dealing with conversion was published in 1896 by James Henry Leuba, shortly followed by others (William James, Edwin Diller Starbuck, Granville Stanley Hall). There was a strong connection between early psychological theorizing about conversion and Protestant theology linked to (1) uncritical adoption of theological terms and concepts which were treated as scientific, (2) overemphasizing the essential nature of religious experience (conversion) as the heart of religion and its sole positive outcome, (3) separating conversion from other social and cultural aspects of human life leading to a broadly criticized *sui generis* approach and phenomenology of religion, and (4) overestimating the solely private character of religious experience and giving preference to introspection. The *sui generis* approach holds that religion (and religious experience) has its own inherent essence and cannot be reduced to anything else. Since religion is a wholly different and unique phenomenon neglected from the cultural and social reality, it deserves its own category, different research methods, and understanding. James privileged religious experience over the other constituents of religion (group, doctrine, or practice) and considered conversion as universal, one of the most genuine and authentic religious experiences. In his view, conversion is a matter of adolescent psychology, an event of self-unification that was always highly positive for the subject. This focus on the positive relationship between the conversion and mental and physical health, self-esteem, and well-being is characteristic of psychological conversion study till present-day. Conversion is by definition a positive change, and there is little interest among scholars in the negative religious change.

Sociological Conversion Studies

After a period of domination psychology in conversion studies followed by a short silence sociology came into play. This was caused by the emergence of a very popular but scientifically useless and fallacious brainwashing models (Robert Jay Lifton, Edgar Schein) and new religious movements (NRMs). Sociology with its gradual-vanishing-of-religion paradigm was surprised and fascinated by NRMs' broad social impact. This brought new issues into the spotlight. Sociological conversion research was predominantly focused on religion and ► [socialization](#) processes (Jeffrey Hadden, Theodore Long), deprivation (strain) theories (Rodney Stark, William S. Bainbridge), and social nonconformity issues (John Lofland). Broadly used drift models (John Lofland, Rodney Stark, James Downton), which assumed a step-by-step conversion process gradually fulfilled by active individual, showed that there is nothing special about conversion. It definitely lost its solely individual psychological character based on a universal religious experience category, and it started to be treated primarily as a social process related to group membership, commitment, ideological affiliations, or recruitment efforts of crucial importance to established social networks. The universal Jamesian "core experience" behind culturally conditioned expressions was being challenged. Facing various non-Christian religious movements, conversion failed to maintain its homogenous nature based on the Pauline model and lost its "once and for all" character. These facts quite seriously damaged the perennial assumptions about conversion, mainly its autonomy and distinctive religious nature. On the other hand, conversion seemed to be an issue too complicated to assign to an unstable category of membership (Arthur Greil, David Rudy), and "drift models" were valid only in the specific religious historical contexts of particular religious movements. Later on, scholars' concern shifted from conversion-as-membership to conversion-as-identity and discourse change (Richard Travisano, R. Kenneth Jones).

The Way We Talk About Conversion

Despite significant theoretical shifts, conversion as a radical transformation of identity or orientation has been preserved by a distinguishing between profound, permanent change and less serious, noncomplex, and reversible alternations (Arthur Nock, David Gordon). These dichotomies enable a differentiation between many types of religious changes, but they are not able to tell us how much change one needs for conversion to take place. They define what conversion is not in more detail than what it is. Some authors (David Snow, Richard Machalek, James Beckford) stressed the need for certain empirical indicators of conversion and criticized scholars' uncritical reliance on converts' stories, thus ignoring the situational context of these linguistic expressions, since converts' verbal accounts are always retrospective and there is no way to study conversion "live." Resulting models and theories are "ideal typical natural histories" of a particular religious group and its adherents, not causal models of the conversion process. A neophyte tries to establish herself as full-blown member; she learns how to express and talk about her own experiences in accordance with the movement's rationale (Snow-Machalek 1983). This reflects the narrative approach to religious experience in sociology (David Yamane) and conversion studies (Peter L. Stromberg).

Current Approaches to Conversion

In psychological conversion studies, psychoanalytical approaches were established (Chana Ulmann), ► [meaning-system analysis](#), which refers to the analysis of interactive set of person's cognitive, affective, behavioral, and motivational elements (self-perception and identity life purposes, attitudes and values, concepts, attributes, goals, sensitivities, ultimate concerns, etc.) that are undergoing change in the process of conversion (or spiritual transformation) (Raymond Paloutzian), ► [attachment theory](#) (Lee Kirkpatrick, Phillip Shaver), and

► [attributional theory of religion](#) (Bernard Spilka, Kenneth Pargament, Phillip Shaver, Ann Taves). Margit Warburg, inspired by the methods from history, deals with the possibility of obtaining sociological data from converts' narratives (Warburg 2008). The way we look at conversion today is influenced mainly by sociological social psychology and the cognitive science of religion (Illka Pysiäinen, Fabrice Clément).

Conversion in "Science and Religion"

Conversion is undoubtedly a doctrinal construct of Protestant theology, and as such, it was introduced to social sciences. Before any scientific study of religion was established, conversion was studied in the area of missionary studies and practical theology. Nowadays, scientific findings about conversion are being used in missiology, and missionaries graduated in anthropology often participate in conversion studies (Paul Hiebert) (Rambo 2003). Theology still occupies an important place not only in understanding and shaping of conversion experience, but also in its explanation. The development which went from conceptualizing conversion as a *sui generis* religious experience to its subsequent challenging by cultural pluralism thanks to NRMs and non-Christian religions, ended in "the linguistic turn," which gradually disrupted the term's autonomy. Since there is no religious organ or brain region (as **neurotheology** holds), or special social or psychological process equivalent to conversion, there are many ways of studying and defining it, and a general theory of conversion is unlikely to emerge. The only exception is the holistic model of Lewis Rambo who attempts to include everything from later psychological and drift models and creates a universal theory (Rambo 1993). Behind attempts to uniformly conceptualize conversion as a homogenous phenomenon at its core, despite heterogeneous features on the surface, there is still a metaphysical presumption about its autonomous nature. Conversion is studied non-theologically, although there are often background theological assumptions about the human condition and

purpose of life. In method and theory debates, a theological-friendly approach is usually linked to refusing any kind of reductionism or naturalistic approach, preserving the phenomenological nature of conversion and preferring first-person methodologies. Conversion concepts narrow our focus on "world religions" with a systematic doctrine to adopt and unified practices to follow in conversion process, even though this is not the case of most religions. The dynamics of the conversion concept in "science and religion" can be also seen as a result of the term's transition between two distinctive meta-representational contexts.

Cooperative Game Theory

Gómez González Daniel
Universidad Complutense De Madrid, Madrid,
Spain

Game theory is divided into two branches called the noncooperative and cooperative. The main difference between these two issues is how it formalized the communication or interdependence among the players. In cooperative theory, it is usually assumed that there is no communication among players and the mathematical model describes only the output that results when the players come together in different roles.

In the noncooperative theory, it is assumed that there is communication between players, and one of the main aims is how to allocate the benefits or loss of the group among its members.

Coping

Carolyn M. Aldwin and Michael R. Levenson
Program in Human Development & Family
Sciences, Oregon State University, Corvallis,
OR, USA

Coping refers to the processes by which individuals attempt to manage stressful situations and their attendant negative emotions. Currently, there is no consensus as to how many types of coping strategies exist, but in general there are three overarching types: problem-focused

strategies that are directed at resolving or managing the problem, emotion-focused strategies that are directed toward regulating emotional responses, and meaning-making strategies that focus on incorporating stressors within existing worldviews and/or altering worldviews to accommodate new perspectives. Strategies in all three types of coping may be behavioral or cognitive. Coping typically occurs within a social context. Individuals may directly access social support, either for tangible help in managing the problem, assistance in emotional regulation, or for general advice, or engage in dyadic coping. The outcome of individuals' coping efforts affects not only their own well-being but also that of others, generally in the immediate social context, but sometimes in the larger socio-cultural arena.

Definition

Religions coping is a multifaceted construct reflecting a variety of ways of bringing one's religious life to bear on stressful experience. It typically includes strategies such as prayer and/or meditation, relying on God, and reading religious texts for guidance. In general, religious coping is often adaptive and can lead to preservation of physical and emotional health, and a greater sense of self-efficacy. However, it is possible to distinguish helpful from harmful kinds of

religious coping. Pargament argues that the most important difference between them may be that in helpful religious coping, there is an experience of collaboration with the transcendent or divine to cope, whereas in harmful religious coping, “anger at God” or a feeling that one is being punished predominates.

Coping: A Brief History

Coping is a discipline that grew out of psychoanalysis and its study of defense mechanisms. However, psychoanalysis focused solely on unconscious strategies that people use to ward off anxiety and neglected conscious, purposive strategies that individuals use to modify their environments, their responses to the environment, and their internal emotional states. Early studies of coping styles focused on trait-like perceptual processes, such as attending to the problem (approach or monitoring) or avoiding the problem (avoidance or blunting). These were assumed to be characteristic ways of dealing with all problems. However, researchers such as Richard Lazarus questioned how consistent individuals were across situations and argued that coping consisted of conscious choices that individuals made in the face of environmental demands. Thus, coping processes consist of efforts that individuals make to manage a specific problem and the attendant negative emotions. Not all coping researchers agree that all coping is voluntary and refer to involuntary actions such as crying or swearing. Yet others argue that these are immediate emotional responses that should be distinguished from coping efforts.

There is currently no consensus as to exactly how many coping strategies there are. Most researchers acknowledge two broad overarching strategies – problem-focused and emotion-focused coping – but within these broad categories, there are many finer-grained distinctions. Most researchers acknowledge common strategies such as escape/avoidance, withdrawal, seeking support, substance use, and cognitive

reappraisal. The latter is sometimes referred to as meaning making. But there are many other strategies currently under investigation, including religious coping and providing social support to others, as well as other strategies that may be addressed to specific problems. Other researchers distinguish between emotional expression and emotional processing (i.e., what am I feeling and why?).

Two recent developments are noteworthy. The first is the recognition that coping does not occur in a psychological vacuum – rather, most coping takes place in a social context. Dyadic coping refers to joint efforts to manage problems that pairs of individuals – generally couples – make, usually with chronic stressors such as serious illness. Again, there is currently no consensus as to what dyadic coping entails. Some researchers identify four broad categories, ranging from non-involvement, to the provision of emotional or instrumental support, to collaborative efforts, and to domination or control by one of the partners. Others refer to relationship-focused coping, which consists of empathic coping – recognizing the other’s needs and adjusting one’s responses accordingly – and compromising. In other words, chronic stressors impact both members of the dyad, and partners make decisions as to what extent and how they are involved with each other’s problems. Further, the relationship in the context of the stressor must be managed as well.

The second major trend is to broaden the range of coping from dealing with an immediate, specific situation to dealing with potential problems. This includes proactive strategies to prevent or mitigate the occurrence of a stressor in the relatively near future, such as studying for an upcoming examination, and anticipatory coping, which is the accumulation of resources to prevent future problems, such as going to college to get a better job.

Self-identification

The purpose of coping is to buffer the adverse effects of stress. After several decades of

research, most scientists acknowledge that stress can have adverse psychological and physiological consequences, including mental illness and disruptions in homeostasis at the cellular and system levels, which can lead to chronic illnesses. However, there are clearly individual differences in the effects of stress, which can be attributed to many factors, including physical or psychological hardiness, social support, and coping strategies. Thus, coping has measurable impacts on health and well-being. The recognition that coping strategies can be learned – and unlearned – provides ample opportunity for interventions to teach individuals new strategies to cope with the challenges that they face.

Decades of research in coping have not led to simple answers. It is fairly easy to identify types of coping that have adverse effects, or which worsen the problem, such as substance use, rumination, or wishful thinking. However, the positive effects of coping are often highly contextual. In other words, the study of coping is complicated by the fact that there are no “silver bullets” – strategies that have positive outcomes regardless of context. This is further complicated by individual differences in coping preferences. For example, some individuals may prefer to cope by ignoring the problem as much as possible (or feasible). Forcing them to engage in information seeking or other problem-focused strategies may result in a worsening of their situation. Thus, coping interventions may need to be tailored not only to individual situations but also to individuals’ preferences. Further, researchers are beginning to understand that coping may have different short- and long-term outcomes. For example, fully engaging in a difficult problem, such as bereavement, may create additional distress in short-term outcomes but result in better long-term outcomes.

Coping as a Distinct Discipline

As a discipline, psychology typically uses four methodologies: individuals participate in controlled experiments; they answer general

questionnaires about their personality, attitudes, values, and behaviors; they can be observed in various settings; or they can be interviewed. Studies of coping processes, however, ask individuals to do something rather different. They are asked about their thoughts, behaviors, and internal emotional processes in very specific, stressful episodes. In our experience, this task is difficult for many people. When asked, “How did you cope with this situation?” respondents, especially men, typically say, “Well, I solved the problem.” Extensive interviewing experience led us to the necessity of having to ask first what emotions they were experiencing and then to ask how they coped with their emotions. Indeed, individuals often do somewhat better using coping checklists, which allow them to recognize cognitions and behaviors that may not emerge spontaneously in coping interviews. Thus, asking individuals to introspect about specific stressful episodes is a unique and difficult methodological problem for coping. This has led some researchers to doubt whether individuals can adequately report on their internal processes, especially retrospectively. Instead, they propose that experience sampling methods, in which individuals are beeped at random intervals during the day and asked to report on their immediate experience, are a more valid way of tapping internal processes. However, others have suggested that well-crafted questionnaires and interviews can elicit valid coping responses, even retrospectively.

Another source of distinction is the emphasis on appraisal processes. In order for individuals to cope, they must first appraise the situation as a harm or threat, loss, or a challenge, or simply as an annoyance. This approach emphasized that adaptation is a function of both the person and the environment, as appraisal is influenced by both personal and contextual factors. This allows the scientific study and recognition of the importance of subjectivity for adaptation. Stressfulness does not derive strictly from situational characteristics but rather is a balance between environmental demands and individual resources. Rather than dismissing subjectivity as a confounding factor

or “noise” in the system, coping research recognizes the central importance of appraisal to adaptive processes.

Relevance of Coping to Religion

Religious issues are increasingly incorporated in coping research. While early researchers ignored the use of religion in coping, its widespread prevalence forced the field to consider the effects of religious coping, such as prayer and reliance on God or a higher level of being. In general, religious coping is associated with better mental health, although its effects on physical health are not as clear. However, there are different types of religious coping, and not all are beneficial. If individuals become passive, or perceive their travails as an indication that God has deserted them, then they may have increased distress and even poorer outcomes such as increased mortality. However, the study of religious coping is still in its infancy. We do not as yet understand the situations in which individuals use religious coping, its effect in different situations, and the similarity and differences in religious coping across different religions.

Sources of Authority

There are several key figures in coping research. Given the vast expanse of the field (over 70,000 published studies), not all important scholars can be recognized here, and we apologize to those whom we may have inadvertently omitted. As mentioned earlier, the study of coping has its roots in psychoanalysis, and Anna Freud (1966) was the most instrumental in identifying different types of defense mechanisms, while George Vaillant (1977) organized them into a developmental hierarchy. Richard Lazarus (Lazarus and Folkman 1984) promulgated the importance of cognitive appraisal in the coping process, and he and his colleagues, notably Susan Folkman, developed one of the first coping scales, based partially on the work by Rudolph

Moos. Lazarus and Folkman also were the first to define coping as adaptive, or responsive to situational demands, and purposive, not simply reactive to those demands. Coping actively reflects the pursuit of individual goals within stressful situations. James Coyne, Anita DeLongis, Stephen Hobfoll, David Mechanic, and Leonard Pearlin extended the recognition of the influence of social situations on the coping process. Importantly, Pearlin (1989) argued that coping was often tied to specific social roles and suggested that the most efficacious coping was that which constrained the stressor to a specific role domain and did not allow it to spread across domains. Carolyn Aldwin (2007), Nancy Eisenberg, Gisela Labouvie-Vief, and Ellen Skinner examined coping as a reflecting and influencing developmental process. Crystal Park (2010) and Howard Tennen have focused attention specifically on the importance of meaning making, while Kenneth Pargament developed a measure of religious coping. Alex Zautra (2003), Peter Vitaliano, and Tracey Revenson provided new insights on how people cope with illnesses, most notably chronic illnesses such as arthritis and cancer. Shelley Taylor (Aspinwall and Taylor 1997) and Lisa Aspinwall proposed proactive and anticipatory coping, which are ways of avoiding or mitigating the effects of stress before they occur. Methodologically, Charles Carver and Michael Scheier (Carver et al. 1989) developed the most widely used coping scale, Annette Stanton developed an improved measure of emotion-focused coping, and Arthur Stone pioneered the use of experience sampling in coping research. Manfred Diehl (1998) and Cindy Berg have proposed a new focus on everyday problem-solving as another way of examining adaptation in late life and have developed measures to further this line of research.

Ethical Principles

Two basic ethical principles guide coping research. First, the types of stressors people often experience are far more severe than can be

replicated in a laboratory setting. Thus, in order to understand how individuals cope with major stressors, researchers must conduct their studies in a field setting. These include studies with patients with serious illnesses, with people who have experienced natural disasters, with soldiers who have experienced combat, and with those experiencing divorce, death of a loved one, or other serious family distress.

The second principle is an understanding that having individuals recount serious stressors can be extremely stressful in itself. For example, asking veterans to recount trauma experiences or rape victims to recall their attacks can evoke episodes of posttraumatic stress. Thus, research conducting retrospective studies of major stressors should have clinicians for referrals in case their respondents experience serious stress responses.

Key Values

The key value of stress research is ultimately to reduce distress and to promote mental and physical health. Stress is ubiquitous; all individuals will experience major stressors at some point (or at many points) in the course of their lives. The major assumption is that the ability to cope with stress and to mobilize existing resources can protect individuals' mental and physical health or enhance their well-being in the face of inevitable physical decline.

Major Conceptualizations

Stress is a ubiquitous part of the world, and ► [nature](#) has developed means of protecting organisms against stress. Every living being, from single-cell organisms to mammals, shares certain stress protection mechanisms, such as heat-shock proteins that protect and repair damaged genes, as well as direct dismantling of cells which are too damaged to repair. According to theories of hormesis, cells and organisms that have been stressed but which recover may display greater resilience to future stressors. Protection against the effects of stress is so important that

organisms have developed multiple and somewhat redundant systems to protect themselves.

In many ways, humans are the most stress resistant of the creatures on earth. As Rene Dubos stated, humans' greatest advantage – adaptability – is also our greatest disadvantage. Humans have devised means to tolerate stressful conditions which would result in the death of most other creatures, but doing so can come at serious costs, such as creating major chronic illnesses and much unhappiness at the individual level, strain at the sociocultural level, and, one could argue, at times environmental degradation, as we strip the earth of resources to support massive populations and to maintain the infrastructure that permits humans to live all over the planet, including in extreme environments.

A major focus of humans coping with stress is what some would call *meaning making*. From a spiritual point of view, which posits the inherent meaningfulness of life, a more appropriate term might be *meaning finding*, also known as ► [discernment](#) in some religious communities. If ► [life](#) is inherently meaningful, then ► [death](#) is also inherently meaningful. Individuals' understanding of the meaning of death affects how they cope. For those who believe in an afterlife, either reincarnation or some higher level of existence, how one copes with stress (temptation, suffering) affects who or what they will become in the next life. For those who believe that the present life is unique, death can provide meaning to life. Understanding that life is limited can encourage individuals to make the most of the life that they do have and to focus more on the positive aspects of stressful situations than to dwell on the negative aspects.

In the process model of stress and coping, the key element is appraisal, or the meaning an individual derives from the experience. Appraisal represents a transaction between what an individual brings to the situation and the characteristics of the situation. Thus, it would not be too great a stretch to say that this approaches a nondual model of reality and ► [consciousness](#). In other words, experience and ► [perception](#) are central, and there is a continuity of experience that renders the boundaries between the self and the rest of the world provisional – an understanding that

one's appraisal of the situation is not "objective" but embraces subjectivity.

From a developmental perspective, an individual's knowledge base is built up through experiences, many of which are stressful. In these situations, individuals often must increase their knowledge not only of the situation but of themselves as well. We must be able to evaluate our strengths and weaknesses, and according to stress-related growth theory, our assumptions about the world and our place in it can become more apparent. An increase in knowledge can be accompanied by a decrease in stress. Either one now has sufficient resources to meet challenges, or one can gain perspective through which one recognizes that many, if not most problems, are self-limiting and, in the grand scheme of things, not terribly important – in short, reflecting the saying attributed to Jesus: "The ► [truth](#) will set you free" (John 8:31–32).

The relationship between ► [time](#) and the stress and coping process is complex. On the one hand, stress and coping processes play out over time, but they can also alter one's perception of time. For example, in highly stressful situations, time can appear to slow down tremendously, as when soldiers report that they watched a bullet coming toward them. In situations characterized by too little stimulation, time appears to expand and slow down, while in those characterized by overstimulation, time can appear to mysteriously speed up. In other words, stress can alter the perception of time, often quite dramatically.

Jung said there was no conflict without ► [consciousness](#). Inverting this, one could say that stress may be the birth of consciousness. In other words, awareness derives from the original stress of encountering the world. The ethos of Western approaches to coping focuses on ► [rationality](#) and reason – in other words, one "should" use problem-focused coping to analyze the situation, devise a plan of action, and carry it out to solve the problem. However, coping research has shown repeatedly that emotion- and problem-focused coping are tightly intertwined and almost always co-occur. Emotions can provide the motivation for coping, and internal regulation is a sine qua non for effective

action in the world. Once again, the stress and coping process paradigm can be seen as quite usefully synthesizing apparent opposites.

If there is a mystery in coping, it is that, from conflict between self and world, the nonduality of self and other can be experienced and can provide the key to coping. As Henry Bayman remarked, "whatever you do, you do to yourself." This can be a most practical mystery.

[Astronomy](#)

Description

Cosmology is the study of the origin, evolution, fate, composition, and large-scale structure of the Universe as a whole, as a complete entity in its totality. Contained within cosmology is cosmogony, which deals with the origin and evolution of the contents of the Universe, such as black holes, stars, galaxies, clusters of galaxies, and quasars. Astronomers provide data for observational cosmology, which deals with the large-scale properties of the observable Universe. Important astronomical constraints to modern cosmology are the discovery that the galaxies are receding

in every direction, away from us and each other, at speeds that increase with their distance; the discovery of the cosmic microwave background radiation, with its thermal black body spectrum and extraordinary isotropy of one part in 10,000; and the observed abundance of hydrogen, by far the most abundant element in the observed Universe, and helium, the second-most abundant element. All of these observations are best explained by the Big Bang cosmological theory, in which the expanding Universe arose from an exceptionally hot and dense state about 14 billion years ago. The background radiation is interpreted as the relic of the dense, hot radiation that preceded the formation of matter; the radiation has now cooled to just 2.7 K. Nucleosynthesis during the first three minutes of the Big Bang accounts for the formation of hydrogen and most of the cosmic helium, as well as deuterium and lithium. A key conclusion of modern cosmology is that the observable Universe has a history, and that we can trace its evolution from the Big Bang to the present by looking back into time when the radiation from distant objects was emitted. Recent developments in observational cosmology include evidence that the Universe contains substantial amounts of invisible dark matter, which might amount to up to 25% of the mass of the Universe. The presence of this unseen material is inferred from observations of visible galaxies, but there is no current consensus about its detailed properties. Observational cosmologists are also probing the large-scale, three-dimensional distribution of galaxies using redshift surveys such as the Sloan Digital Sky Survey. Wherever they look, in whatever direction and near or far, they find walls, chains, and filaments of galaxies of up to a billion light-years across, together with seemingly empty places known as voids, of about 100 million light-years in diameter. Observations of supernovae in distant galaxies indicate that the expanding Universe is accelerating or speeding up as it flies apart, rather than slowing down, pushed apart by some mysterious dark energy. Instruments aboard the *Wilkinson Microwave Anisotropy Probe* satellite have been used to detect temperature fluctuations, or ripples, in the

angular distribution of the background radiation, providing constraints to cosmological models and investigations of how the first stars and galaxies formed. Theoretical cosmologists use mathematical equations to describe models of the expanding Universe, usually incorporating Einstein's *General Theory of Relativity*, with or without an adjustable cosmological constant that counteracts gravity and affects the rate at which the Universe expands. The models usually include the cosmological principle, which states that on the largest scales the observable Universe is isotropic and homogeneous, so that it looks the same at any location and there is no preferred place in the Universe. Recent cosmological models use studies of supernovae, galaxy clusters, and the background radiation to put constraints on dark matter, dark energy, and the cosmological constant.

Self-identification

Science

Observational cosmology self-identifies as a science that measures the large-scale physical properties of the observable Universe in its entirety. It usually assumes that celestial bodies obey identical physical laws to those on Earth, such as the laws of universal gravitation and the *General Theory of Relativity*. Some theoretical cosmologists use these laws to explain cosmological observations, and they can design future observational tests of their theories. Other theoretical cosmologists are preoccupied with the mathematical equations and related cosmological models, sometimes with little regard for observational cosmology.

Religion

The origin of the Universe is one topic in which modern cosmology and religion overlap. The Big Bang cosmology provides a good account of the evolution of the Universe since about 14 billion years ago, but no cosmologist knows for certain what happened before that. Their equations break down at that first moment, blowing up into infinities of density, temperature, and the curvature of

space-time. Some cosmologists say that we will never have direct observational evidence for what happened before the Big Bang, which may have obliterated any evidence of previous space, time, or matter. So cosmological speculations about how the observable Universe came into being, and where everything came from, bear no more authority than most of the world religions whose creation myths explain the beginnings of the Universe and life. For most of history, cosmology has indeed been part of mankind's religious rather than scientific view. This has not kept some theoretical cosmologists from proposing an ultimate theory that will eventually explain why the Universe exists, even invoking a God particle or stating that they may eventually know the mind of God, but such a final theory has not been found despite more than half a century of trying.

Characteristics

Observational cosmology is a non-experimental science in that celestial bodies cannot be taken apart or manipulated by controlled experiments in terrestrial laboratories, and cosmological hypothesis can only be verified by passive observations. Some theoretical cosmologists develop models that have little or no definitive observational tests.

Relevance to Science and Religion

Modern cosmology is most likely incapable of answering some basic cosmological questions, which are addressed by religions and lie outside the domain of direct scientific inquiry. These include the origin, fate, and purpose of the Universe. In Saint Augustine's interpretation of the book of *Genesis* in the *Bible*, for example, the Universe was brought into being in a less than fully formed state but gifted with the capacities to transform itself from unformed matter into a truly marvelous array of physical structures and life forms. In 1951, Pope Pius XII endorsed what we now call the Big Bang cosmology, arguing that it demonstrated that the Universe had a beginning

in time and proved the existence of God, the Creator, and the Buddhists have long taught that the Cosmos we live in is only one of an infinite number, and that the Universe never begins or ends, but endures.

Sources of Authority

The ultimate source of authority in cosmology is peer review using known physical laws, mathematical calculations, and verifiable predictions of observational consequences. Any cosmological explanation of celestial phenomena ought to be tested through decisive, new observations that show that the explanation is true or false, right or wrong. Nevertheless, some theoretical cosmologists are not particularly interested in observational constraints to their models, claiming authority in the equations and models themselves.

Ethical Principles

Cosmologists are skeptical, taught to question any discovery and to test it by peer review, and they are trained to employ personal detachment and uncompromising honesty.

Key Values

The key values of cosmology are the physical explanations of the origin, evolution, fate, composition, and large-scale structure of the Universe as a whole, as a complete entity in its totality.

Conceptualization

Nature/World

Cosmologists regard nature as equivalent to the physical world outside Earth, although the natural terrestrial world is used as a foundation for physical laws thought to be applicable throughout the Universe. Nature is supposed to include both known and unknown cosmic objects and

phenomena, either perceptible with contemporary astronomical telescopes or currently unseen and potentially observable with future instruments. Some theoretical cosmologists have suggested that our observable world is just one of multiple Universes that can never be observed, but this is essentially a nonscientific proposal somewhat like a similar Buddhist one.

Human Being

Cosmology does not normally consider either human beings or the pains and pleasures of human life, which are thought to be outside the domain of cosmological inquiry. Cosmologists do determine the contents and structure of the Universe, and by extension humanity's place in it. The Earth and Sun, for example, lie in the outskirts of a perfectly normal galaxy, no different from billions of other galaxies all participating in the expanding Universe that has no observable center or edge.

Life and Death

Cosmologists adopt the discoveries of astronomers and astrophysicists, who have shown that our planet and everything on it are composed of elements synthesized either in the nuclear crucibles of stars that exploded into space before the Earth and Sun formed or before that during the first moments of the Big Bang that gave rise to the expanding Universe. Despite our ability to pry living things apart, identifying their atomic, chemical, and molecular constituents, which can often be found outside Earth, no one has discovered the spark of life, showing how inanimate matter could have been transformed into a living thing, either on our planet or elsewhere. Astrophysicists forecast that life on Earth will not last forever, and that the entire human race is scheduled for extinction in a few billion years when the brightening Sun will vaporize the Earth's oceans.

Reality

To most cosmologists, the real Universe consists of the currently observable one, but they often believe in a yet undiscovered, invisible reality

that lies beyond the visible one and includes all that exists. Some cosmologists are immersed in a paper world of theories that describe their reality, but some astronomers would say that their perspective has become blurred by mathematical equations and is disconnected from the real, observable Universe.

Knowledge

Cosmologists regard knowledge of the Universe as a cumulative, ongoing process of the discovery and explanation of its large-scale ingredients and their collective behavior.

Truth

Most cosmologists believe in an objective, scientific truth verifiable by decisive observations and significant tests. Others hold that cosmological models and related mathematics can also provide true descriptions of the Universe.

Perception

Observational cosmologists use new technology and novel telescopes to extend the capacity of their physical senses, thereby perceiving, becoming aware of, and eventually understanding otherwise invisible physical properties of the large-scale Universe. These perceptions are repeatable, and can be obtained by anyone using the same or similar instruments. Some cosmologists regard mathematical extrapolations of existing physical laws as another method of perception.

Time

Because light travels at a finite speed, astronomers look back into time when observing distant objects. Powerful telescopes are therefore used as time machines to see objects as they were in the past, when their light was first emitted. The general conclusion is that everything in the observable Universe is changing, arising in one form, evolving into other ones, and eventually passing away to be replaced by something else. Observational cosmologists are, for example, now tracing the history of the expanding Universe back to the first moments of the Big Bang, when fluctuations were imprinted in the background radiation and

soon thereafter when the first stars and galaxies were formed. No cosmologist knows for certain what happened before the Big Bang, and time might have even begun with this creative event.

Consciousness

To a cosmologist, consciousness is the mental awareness of the surrounding Universe, involving the perception of its large-scale properties that might be explained by known physical laws.

Rationality/Reason

A cosmological concept is normally termed rational if it uses accepted physical laws and can be decisively tested by significant observations. Some cosmologists regard any mathematical extrapolation of existing physical laws as rational.

Mystery

The entire Universe is regarded as a great hidden mystery awaiting discovery and understanding, and its known constituents may also have mysterious aspects that remain to be examined and understood. The ultimate origin of the Universe remains shrouded in mystery, as do the properties of dark matter and the mysterious dark energy.

Relevant Themes

There are many critical, unanswered questions about the Universe that lie outside the domain of cosmology, and are concerns of religion. They include the origin and fate of the Universe and life within it, and the purpose of either one of them. No cosmologist knows for certain what happened before the Big Bang, or how the observable Universe came into being, and they do not know if life originated from inanimate matter, or exactly what might have provided the spark of life on Earth. And owing to the recent discoveries of dark matter and dark energy, which we know almost nothing about, the eventual fate of the observable Universe remains unknown, despite the fact that distant galaxies are now accelerating into invisibility.

Description

Counseling psychology is the study and application of psychology for the purpose of promoting well-being, alleviating psychological distress, and resolving crises in individuals, families, and groups. A central aspect of counseling psychology is the therapeutic relationship between a mental health professional and a client, and facilitation of personal and interpersonal growth in various areas (emotional, social, vocational) throughout the life span. Although counseling psychology has been closely linked with clinical psychology, subtle differences exist between these subdisciplines; counseling psychology tends to focus on less severe ▶ [psychopathology](#), and counseling psychologists are more likely to theoretically assume a humanistic perspective when working with clients.

Counseling psychology's humanistic orientation dates back to Carl Rogers' publication of *Counseling and Psychotherapy* in 1942, which stimulated the development of counseling from a nonpsychoanalytic and nonmedical perspective. Although the history of counseling psychology has been divided into seven distinct periods from 1908 to 1984, it was in 1943 that APA Division 17 was formed and named the Division of Counseling and Guidance (although discrepancies occurred in following years regarding the name) (Whiteley 1999). In 1953, the name of APA Division 17 was changed to Division of Counseling Psychology (and later that year the birth of the *Journal of Counseling Psychology*

was announced – with the first edition being in Feb 1954).

In the past 20 years, counseling psychology has continued to emerge as a unique subdiscipline, with greater focus on viewing people and their behavior within a sociocultural context, influenced by variables of gender, ethnicity, sexual orientation, age, and culture. Recently, there has been increasing methodological diversity and sophistication in the field, as well as an emphasis on multiculturalism and health psychology.

Self-Identification

Science

From its origins, psychology has identified as a science; psychological science is the study of mind, brain, and behavior, and counseling psychology is one of the subdisciplines within this broader study. Counseling psychology attempts to explain and investigate human behavior; it is the science of the personal, the subjective, and the individual. Counseling psychologists strive to make sense of the mind and examine human behavior as the raw data for testing theories and hypotheses about how the mind works. Since the German psychologist Wilhelm Wundt opened the first psychological laboratory in 1879, the field of psychology has continued to utilize the scientific method to learn about the relationship between the mind, brain, and behavior. Empirical methods are increasingly emphasized in the field of counseling psychology, and efficacious interventions are derived from evidence-based studies that employ systematic, objective methods of observation (Gazzaniga and Heatherton 2006).

Characteristics

Historically, counseling psychology has been closely linked to the subdiscipline of clinical psychology. The main difference has been perspective. Counseling psychology assumes a humanistic theoretical approach and focuses on healthy individuals and less severe

psychopathology, whereas clinical psychologists work with individuals with severe mental illnesses and tend to be more medically oriented, focusing on treatment of disease. At the roots of counseling psychology is a focus on prevention (as opposed to intervention), and of growing importance are issues of social justice and multiculturalism. Additionally, counseling psychologists are trained in a wide variety of basic therapeutic skills and are considered to be generalists (i.e., incorporating vocational and career counseling, developmental issues, ► [positive psychology](#), etc.).

Relevance to Science and Religion

Science and religion have often been compartmentalized and seen as two distinct entities. The field of psychology is no exception to this, as there has been historical antagonism between religion and psychoanalytic branches of psychotherapy (Gurney and Rogers 2007). Recently, however, clinicians and scholars in the field of counseling psychology have realized that many clients do not divide their faith from their behavior, work, or relationships, but rather view it as deeply connected to who they are, recognizing that their lives have divine significance (Pargament and Mahoney 2005). Studies provide evidence to the sanctification of sex, body perceptions, and behavioral health patterns, acknowledging the interwovenness between ordinary and extraordinary in the counseling room (Mahoney et al. 2005; Murray-Swank et al. 2005). A growing number of studies indicate a connection between health and faith/religion; religious adults, for example, report more adaptive strategies for coping with life stresses, enhanced feelings of self-efficacy, and a stronger sense of social support than nonreligious adults (Loewenthal 1995). Given counseling psychologists seek to work with clients from a humanistic and holistic perspective, taking into account individual strengths and resources, there are increasing connections between counseling psychology and religion, particularly in regard to ways in which faith enters the counseling room.

Sources of Authority

The notion of counseling psychology from a nonpsychoanalytic perspective arguably dates back to Carl Rogers' publication of *Counseling and Psychotherapy* in 1942 and the formation of American Psychological Association's (APA) Division of Counseling and Guidance (Division 17) in 1943. It was, however, during the Boulder Conference in 1949 that the unique perspective of the professional practice of counseling psychology developed; the theme of prevention was underscored and a contextual approach was emphasized throughout this conference. This was further articulated at the 1987 Georgia conference on the Future of Counseling Psychology (Hage 2003). Thus, a preventative, social-developmental, contextual, and health-based framework emerged as the roots for counseling psychology.

Additionally, the *Journal of Counseling Psychology*, originally published in 1953 (the same year that APA Division 17 changed to the Division of Counseling Psychology), is considered to be a grounding source for the discipline of counseling psychology.

Ethical Principles

Counseling psychologists adhere to the ethical standards established by the American Psychological Association as well as the American Counseling Association. Counseling psychologists who work in K-12 school settings also adhere to the ethical standards purported by the American School Counselor Association.

Key Values

At the core of the identity of counseling psychology is an appreciation of the individual, the subjective, and the agentic and the desire to promote growth and development. Toward that end, the counseling psychologist strives to increase clients' coping skills, foster an awareness of societal barriers to ► [self-actualization](#), and advocate for

a holistic mind-body-environment approach with a focus on prevention (Howard 1992).

Conceptualization

Nature/World

Nature is conceptualized as biological and physiological component of life. Inherited traits, abilities, and capabilities are considered to be part of human being's nature, that is, our genetic "wiring."

Human Being

Humans are biological beings with complex and adaptive brains and minds that enable unique behaviors, such as moral reasoning, decision-making, language, creativity, and cognition. These unique capabilities and behaviors distinguish humans from the rest of the animal kingdom.

Life and Death

Life is considered to be the presence of biological and physiological functions that lead to psychological activity. Debate remains among counseling psychologists about when life begins, within or outside of the womb. Death is defined as the cessation of biological and physiological workings of the mind and central nervous system.

Reality

Psychological scientists define reality as observable aspects of one's environment that involve sensation and perception. Sensation is the sense organs' detection of external stimulus, and perception is the internal representation of the brain's processing of external stimulus. Among counseling psychologists, perception is often emphasized; in other words, it is important to understand a client's subjective experience of reality in order to effectively promote well-being. Mental disorders such as schizophrenia may distort reality.

Knowledge

Knowledge is the accumulation of information related to the world that is gained and acquired. There are both objective (agreed upon and

irrefutable) and subjective aspects of knowledge. Knowledge is used to guide our daily actions, solve problems, and make decisions.

Truth

According to an objectivist view, truth is conceptualized as the objective reality that underlies facts. Constructivists, however, define truth as an individual and subjective construal of reality. A constructivist way of knowing and understanding has gained credence in the field of counseling psychology.

Perception

Perception is the processing, organizing, and interpreting of sensory signals that results in an internal representation of an external stimulus. The human mind actively constructs representations of the world and uses those perceptions to guide actions.

Time

Time is an objective measurement used to sequence events and categorize change in the world. Human perception of time can be variable and subjective, and psychoactive drugs can impair one's perception of time.

Consciousness

Consciousness is defined as subjective, moment-by-moment experiences – an awareness that individuals have of their actions and motivations behind their behavior. Contents (or objects) of consciousness are differentiated from levels of consciousness (sleep and wakefulness).

Rationality/Reason

Human beings employ reason to determine if information or a conclusion is true and, consequently, understand reason as authority. There are two types of reasoning, deductive and inductive reasoning. In deductive reasoning, an individual reasons from the general to specific, using a rule to determine if a conclusion follows logically from the rule; with inductive reasoning, an individual utilizes specific examples to determine if a general principle is valid (Gazzaniga and Heatherton 2006). Reasoning can be impaired in

certain mental disorders, such as schizophrenia, a thought disorder, or dementia.

Mystery

Despite the objectivity of the scientific method, counseling psychologists acknowledge that humans – their mind, body, and behavior – will not be completely understood; the subject matter to be studied in this subdiscipline is far too complex. There will always be a level of mystery, of that which is still unknown, in the field of counseling psychology.

Relevant Themes

Given the focus on the personal and agentic in counseling psychology, it is imperative to acknowledge – moreover, openly address – client belief systems in therapy. For some individuals, religion is salient to counseling, as it is central to their worldview formation, personality, and behavior. Yet, a gap continues to exist between “science and religion” engagement as counseling psychologists tend to compartmentalize the objective, science-based “natural” from the transcendent “supernatural.”

Creation in Judaism

Norbert M. Samuelson

School of Historical, Philosophical, and Religious Studies, Arizona State University, Tempe, AZ, USA

Related Terms

[Creation and science in Judaism](#); [Jewish science and creation](#); [Views of creation in the Jewish culture](#)

Rabbinic tradition makes three central claims about God. He creates the world, reveals his teaching, and redeems the world. Creation names the content of the opening chapters of the Book of Genesis in the Hebrew Scriptures about the origin of everything. Redemption names the content of sermons reported in the various books of the prophets in the Hebrew Scriptures about the end of everything. Revelation is the means by which God communicates to all of humanity through the Jewish people the doctrines of creation and redemption. It is generally accepted in all forms of Judaism that the Hebrew Scriptures are a record of revelation. All meanings of all three concepts are interrelated and constantly changing through Jewish speculative writings about Kabbalah and natural philosophy. Of the three the doctrine whose meaning is most closely tied to the intellectual history of the sciences is creation, for it is the only one of the three that has its own distinct scientific discipline – physical cosmogony, which deals with the origins of the cosmos. Creation is in fact discussed in a variety of biblical texts (notably Ex 40:12–25, Ps 74:12–17; 104:1–35, and Job 26:7–14; 38:4–30:30), but the most thorough or detailed presentation occurs in Gen 1:1–2:3. This text divides itself into a series of distinct sets of events each of which it calls “day” or “day and night.” Each day describes a layer of the universe, which, taken together, is the seven layered reality that the text calls “the sky (shamayim) and the earth.”

At the base of reality is the layer of the universe before divine intervention. At this level there exist (presumably from eternity) a “deep” (tehom), darkness, the earth surrounded by waters, something called “tohu and vohu” (often translated as what is “null and void”), and a divine wind (ruah elohim). On day 1, God begins his action by declaring orders to the pre-world existent objects. Each day marks a specific commandment, the obedience to which at the end of the process initiates our physical and living worlds. God’s first command is for there to be a substance, “light” (which is the only one God actually makes) by which he divides the region of darkness infested with light into two separate regions of space, and names them “day” (viz., the distinct region of light) and “night” (viz., the distinct region of darkness). The rotation from any fixed point at the center of the universe allows a continuous repetition of day and night. Each cycle is called a “day,” and the layers of creation are seven. The unit of seven complete days is called the week. Creation’s last day is called “the Sabbath.”

Day 1 produces the basic separation into distinct periods of days and nights. Day 2 produces the sky above the earth. These two most general regions of the space of the universe are themselves kept separate by a universal ring called a “raqiyyah.” In Genesis 1:6ff this divider is called what is commonly translated into English as “a firmament” but really means something that can be stretched out. God acts on this second day by speaking to and making the raqiyyah, and then dividing it into two distinct rings of space, which he named “sky” (shamayim). At this point, the earth appears as a ring at the center of the universe, whose central hole and surrounding external are called “waters,” so that within the central region of the space of the earth, there are the “lower waters” below a ring of earth above which is the “higher waters.” This action completes God’s creation of the regions of space in the universe. What follows is the creation of the “living things” both on and in the universe.

On day 3, God performs two distinct set of acts. One is directed at the waters and the other is

directed at the earth. He tells the waters to collect together into one place and names the region of waters “seas” (yamim) and the region of earth “dry land” (yabashah). Then he tells the earth to sprout forth plants. Day 3 is the transition between the divine ordering of the space of the universe (whose last division is between land and seas) and the divine generation of the inhabitants of that space (whose first production is the plants that stand at the base of what we would recognize as the food chain of all life).

On day 4, God commands into existence the stars (Me-erot, literally lighters, i.e., things made of light) that occupy the sky, whose two purposes in the universe are (1) to differentiate years, days, festivals, and seasons, and (2) to give light to the universe. On day 5, God commands the waters to produce diverse kinds of living (nefesh) swarming things as well as create large sea-monsters (teninim) and all (other) living animals (chayah) that creep and swarm in the waters, as well as every kind of bird (literally “winged flying thing”). Then God blesses them. (“Blessing” is one of at least six things that God does that count as creating; the other five are making, producing, saying, separating, and naming).

On day 6, God commands and makes every living domestic and wild animal as well as everything that creeps (rather than swarms) on land (rather than in the waters). Finally, he creates “the human” (ha-adam) as male and female, and implies that all the other (lower) members of the created chain of being (from plants to animals) exist for him/her as food. (Arguably Judaism has a strong moral emphasis on ways to eat because of its priestly origins).

Finally, God completes his creation of the world on day 7 with the creation of the day of rest (Shabbat). On it he ceases from all of his work (melachah) which he made and rests (shabat).

For all of the rabbis in all of the subsequent periods, whatever this narrative truly means is the full description of the origin of the universe. The problem is what it means. In general, as theologians will say in the nineteenth century, God has two books of revealed nature – science, the book of nature itself, and revelation, the

revealed word of God – and in neither book is the discernment of the true meaning apparent or simple. As nature hides its secrets, so do the Scriptures. Hence, everything depends on how the key terms in the narrative are interpreted, and their meaning is not obvious. In general, the interpretations that different rabbis gave to these terms varied with the kind of world and life views they held, which themselves are greatly influenced by the science of their day. Hence, during the period of the early rabbis, Hellenistic Stoic themes are discernible, as are Aristotelian and Platonic cosmology in the interpretations of the medieval rabbinic commentaries, as are physicalist reductive interpretations in modern commentaries. What remains constant is the list of problematic terms. Here is a list of questions: What are “the deep,” “tohu and voahu,” and the “divine wind”? What is a “day”? Is it a period of time or a spatial division? What is the “light” created on the first day, how does it differ from the lights of the stars created on the fourth day, and where is the original light now? What is a “raqiyyah”? In what does it consist and how does it function to separate the earth from the sky? What is life (nefesh chayah)? What is a “human” and what does it mean that he was created male and female? Finally, how do “work” (melachah) and “rest” differ and how does that difference affect Jewish worship on the seventh day? Note that on any of the ways that the rabbis interpret these creation texts, their meaning integrates physical accounts with judgments about both moral and liturgical purpose.

[Creation; Evolution; Science and religion](#)

The term “creationism” needs to be carefully defined. The historic Christian creeds speak of God as “creator of heaven and earth.” The Hebrew Bible also begins by referring to God’s act of creation, and the Qur’an speaks of God as creator, in terms that echo the biblical account (e.g., Qur’an 7:54). So if we define a “creationist” as one who believes that God is the creator of everything that exists, then all orthodox Christians, Jews, and Muslims are creationists. For the purpose of this entry, however, the term

“creationist” will be used more narrowly. A creationist, in this sense, holds that belief in God’s creative activity is incompatible with an entirely natural explanation of the origins of the universe and of human beings. While some creationists merely assert their belief in a divine creative act, others offer arguments for their view. They insist, for instance, that the proposed natural explanations on offer – such as a naturalistic “Big Bang” cosmology or Darwin’s theory of evolution by natural selection – are inadequate. More generally, they insist that no account of origins that does not make reference to divine activity can be regarded as satisfactory.

The creationist view, so defined, is more widely held than many non-creationists realize. A 1991 Gallup poll in the United States reported that 47% of Americans believed that “God created man pretty much in his present form at one time within the last 10,000 years.” By 2005, the figure had risen to 53%, while nearly two-thirds agreed that creationist account of origins should be taught alongside evolution in public schools. Nor is its impact restricted to the United States, as some critics fondly imagine: it has become a global phenomenon and has spread beyond the boundaries of Christianity. Even in apparently secular and skeptical European countries such as Switzerland and Germany, “young-earth” creationists – those who believe the earth to be less than 15,000 years old – represent about 20% of the population. Among Asian countries, Korea now has a flourishing and influential creationist movement. While modern creationism has Christian origins, by the late twentieth century it had also spread to Islam (particularly in Turkey) and among orthodox Jews worldwide.

In the history of religious thought, the creationist view is both traditional and novel. It is traditional in that before the seventeenth century most Jews, Christians, and Muslims did assume that the world had its origins in a miraculous divine act. Jews and Christians, whose Bible offer the elements of a universal chronology, further assumed that this creative act had occurred about 4000 BCE. The idea that the earth may be enormously older than the biblical chronology suggests, or that Adam and Eve may

have had ancestors, was widely rejected until well into the nineteenth century. To this extent, modern creationism is the revival of an ancient view. But modern creationism differs from this ancient view in at least one respect. Before the seventeenth century, existing bodies of secular knowledge could be more or less easily fitted into a biblical framework. The intellectual revolutions of the seventeenth century broke that framework apart, so that today’s creationists find themselves opposing what most scientists regard as well-established theories.

Science and Religion

With regard to science and religion, creationists are among those reject what Stephen Jay Gould described as the NOMA thesis: the idea that science and religion represent “non-overlapping magisteria,” distinct teaching authorities which cannot come into conflict (Gould 1997). A popular version of the NOMA view holds that science deals with matters of fact, while religion deals with issues of value. Creationists also reject the idea that scriptural statements regarding creation should be interpreted in a purely metaphorical manner or in so general a fashion as to avoid any conflict with proposed natural explanations. With regard to the origin of species, for example, creationists reject the position known as “theistic evolutionism” (a version of which is known as “evolutionary creationism”). Theistic evolutionists accept that evolution by natural selection can explain the complexity and diversity of living organisms, but insist that God was guiding this process. In defending this view, they often appeal to the traditional distinction between “primary” and “secondary” causes: the idea that even a natural process can be providentially guided. Creationists, however, reject such reconciling strategies.

Many atheists, it should be noted, also reject the NOMA thesis. They take their stand on the side of science and reject competing religious claims. Creationists, by way of contrast, take their stand on the side of religion and reject competing scientific claims. Nonetheless, most

modern creationists do not consider themselves to be rejecting science as such. Indeed, they often claim that they are offering a reformed or revised form of science, sometimes called “creation science.” Opponents of creationism sometimes suggest that this is merely a way of avoiding the implications of a constitutional separation of church and state, since it enables creationists to claim a place for their views, *as* science, in the public school curriculum. However, many creationists do believe their position to be “scientific,” in the sense of defensible by reference to observation and experiment. Whether they are correct in this belief is, of course, another question (see [Evaluation](#)).

If creationists consider their position to be scientifically defensible, how do they explain the fact that so many scientists disagree? Most commonly, creationists argue that the modern scientific consensus represents faulty science, based on false or at least unwarranted assumptions. Some of these assumptions have to do with the particular methods used by scientists. Young-earth creationists argue, for example, that the practice of radiocarbon dating rests on unwarranted assumptions regarding the amount of carbon dioxide in the oceans and atmosphere and the rate of formation and decay of radiocarbon atoms. Other allegedly false or unwarranted assumptions are more philosophical in nature. Intelligent design supporters, for instance, argue that contemporary science is distorted by its commitment to a “methodological naturalism,” which rules out *a priori* all reference to divine agency (Johnson 1995: 105). It follows that creationists do not generally claim to be against science as such; what they oppose is what they claim to be a crippled or distorted form of science.

Varieties of Creationism

Despite their shared opposition to exclusively natural explanations, modern creationists hold to a variety of positions regarding the origins of the earth and of human beings. Leaving aside extreme positions such as flat-earthism and geocentrism – from which creationists generally

distance themselves, even when they are held on religious grounds – one can distinguish four positions within the creationist camp. The first distinction to be made is that between old-earth creationism (OEC) and young-earth creationism (YEC), the latter being the most widespread form of contemporary creationism. Intelligent design theory (ID) may be regarded as a third category: In some respects, it resembles a traditional OEC, but it has other, distinctive features. A final form of creationism exists on the cusp between creationism and theistic evolutionism. It accepts natural explanations of the origins of the human body but insists that the human soul was directly created by God. I shall refer to this last position as a “divine animation” theory (DA).

Old-Earth Creationism

Old-earth creationism is characterized by the belief that although the earth and human beings have their origins in miraculous divine acts of creation, the earth is significantly older than a strict adherence to the biblical chronology would allow. By the end of the nineteenth century, this had become the dominant view among both believing scientists and Christian theologians. Beginning with the work of geologist James Hutton (1726–1797), whose natural history notoriously found “no vestige of a beginning, no prospect of an end,” and continuing with that of Charles Lyell (1797–1875), the idea of the “antiquity of the earth” was increasingly accepted. The most common response of both Christian scientists and theologians was to accept this new knowledge and reinterpret Scripture to avoid any conflict with it.

The old-earth creationist attitude was, perhaps, first clearly expressed in a letter of the astronomer and philosopher of science John Herschel to Lyell in 1836: “Time! Time! Time!—we must not impugn the Scripture Chronology, but we *must* interpret it in accordance with *whatever* shall appear on fair enquiry to be the *truth* for there cannot be two truths” (Cannon 1961, 308). By the beginning of the twentieth century, the attitude was widely shared. Even William Bell Riley (1861–1947), one of the first self-styled “fundamentalists” and a staunch

opponent of evolution, rejected the idea that Christians must believe the earth to be only 6,000 years old, holding that “the plain statement of Genesis . . . leaves latitude for millions and even billions of years” (Larson 1997, 223).

Some of the nineteenth- and early twentieth-century scientists who accepted the antiquity of the earth had no interest in reconciling their view of creation with the biblical account. An example would be Louis Agassiz (1807–1873), whose view of creation was, from a Christian perspective, highly unorthodox. But among those scientists and religious thinkers who did attempt a reconciliation, various strategies could be employed. The best known were the “gap” theory and the “day-age” theory. The former held that a great expanse of time – enough to accommodate the geologists’ findings – lay between the creative event told of in the first verse of Genesis and that spoken of in the rest of the biblical account. The latter held that each “day” of the 6-day Genesis account represented, not a 24-h day, but a long period of earth history. A third view – the “pictorial-day” theory – held that the creation of the world was *revealed* (rather than *brought about*) in six days.

What this means is that old-earth creationists were (and are) often rather vague about the details of God’s creative act. On the eve of the publication of Darwin’s *Origin of Species* in 1859, most naturalists still believed the origin of species to be supernatural. But if asked for details, many of them “would plead ignorance of the means and affirm only the fact” (Gillespie 1979, 21). Those who did speculate about the manner in which God created the earth came up with a bewildering variety of schemes. The only thing that united them was the conviction that creation involved miraculous divine acts, whatever form those acts may have taken.

The old-earth creationist position finds expression today in what is sometimes called “progressive creationism.” This holds that while the earth is indeed ancient, and its various forms of life have appeared only gradually, they have done so by a series of divine creative acts. In particular, progressive creationism denies the possibility of “macroevolution,” in the sense of a natural

process that leads to the formation of entirely new types of plants and animals. It insists that the basic kinds of plants and animals were created by a series of divine creative acts, although some variation among these kinds may then have occurred by way of natural selection. Despite conceding the possibility of “microevolution”, this view remains a form of creationism, as defined above. It denies the possibility of an entirely natural explanation of human origins.

Young-Earth Creationism

Young-earth creationists, by way of contrast, insist on a more or less strict adherence to the biblical chronology and what they regard as the literal sense of the biblical record. The implications of biblical chronology are not, of course, immediately evident, so their estimates of the age of the earth vary. But it is safe to say that no young-earth creationist holds the earth to be more than 15,000 years old. Nor do they agree about precisely how God is supposed to have acted. They have offered, for instance, a bewildering diversity of accounts of the biblical flood, which is thought to have been caused by

the eruption of a subterranean abyss, caves in mountains, oceanic tides caused by comets, rain from a comet, realignment of the earth’s center, depression of the abyss by the ocean floor, collapse of a vapor canopy, collapse of an icy asteroid on earth’s surface, eruption of supergeysers from the earth’s core, collapse of a ring of icy particles, [or the] tilting of the earth’s axis by bombardment of asteroids with subsequent displacement of its oceans. (Young 1987, 31)

So it would be wrong to regard even YEC as a single “theory.” Nor should YEC be regarded as a simple continuation of premodern beliefs. It does resemble what most Jews and Christians believed before the seventeenth century, but by the late nineteenth century the young-earth view had been largely abandoned, at least by educated Christians. It follows that YEC is not a simple continuation of the ancient position; it is a recent revival of it, in a more assertive form and a different intellectual context. That revival began with the work of the Seventh-day Adventist thinker, George McCready Price (1870–1963). Early Adventists had held to

a literal reading of the biblical creation story, which was supported by the visions of their founder, Ellen Gould White (1827–1915), and reinforced by their beliefs regarding the Sabbath. Price follows them in this respect but sets out to revive the idea that Noah's flood had played a key role in the formation of the geological and fossil record. Indeed, he argues that only a catastrophic event such as biblical deluge could explain that record.

Price was no means the first to hold to a "catastrophist" view of earth's history, nor was he the first to attribute geological phenomena to the power of water. At a time when there was still little reason to question the biblical narrative, "diluvialist" thinkers such as Thomas Burnet (1635–1715) had speculated about the origins of the waters of the flood and their role in forming the surface of the earth. In the late eighteenth century, the "neptunist" geology of Abraham Gottlob Werner (1749–1817) had suggested that the earth was originally covered with water, from which rocks had formed by a process of precipitation. Although defenders of the biblical account often embraced this view, on account of its apparent resemblance to the biblical story, the origins of neptunism owed little to biblical authority. It was, in origins, a secular theory.

It follows that Price's "flood geology" was very different from Werner's neptunism. Price did present it as a proposal for the reform of geology: he believed it to be the best available explanation of the geological phenomena. But he never denied that its primary inspiration was biblical. Indeed with some philosophical insight, he insisted that the origin of an idea is irrelevant to its assessment as an explanatory hypothesis. If a hypothesis explains the phenomena, it should not be condemned merely because its origin lies in a particular set of religious beliefs.

While the revival of YEC began with Price, it gained momentum with the publication of *The Genesis Flood*, a work coauthored by an evangelical biblical scholar, John C. Whitcomb (b. 1924) and engineer Henry Morris (1918–2006). First published in 1961, this book has become a creationist best seller. In 50 years, it has been reprinted more than 29 times and has

sold more than a quarter of a million copies. In support of their belief in an actual, worldwide flood, its authors engage in detailed biblical exegesis as well as a careful analysis of the geological and fossil evidence in the light of that exegesis. This extends, for example, to a calculation of the gross tonnage of Noah's Ark (13,960 t) and speculation regarding the ways in which so many animals might have been cared for in so confined a space.

Intelligent Design Theory

The most recent incarnation of the creationist position is known as "intelligent design" theory (ID). While there can be no doubt about its religious motivations, ID differs from earlier forms of modern creationism in avoiding explicit reference to the Bible or even the identity of its intelligent designer. "Inferences to design," its proponents argue, "do not require that we have a candidate for the role of designer" (Behe 1996, 196). This strategy, it should be noted, is condemned by many young-earth creationists, who regard it as a kind of cowardly equivocation, as well as by ID's opponents, who regard it as another subtle attempt to smuggle religion into public institutions in the guise of science. Such criticisms, it should be noted, are often *ad hominem*: they attack the character of the proponents of ID rather than their arguments, a fact that is not uncharacteristic of the contemporary debate.

ID's most influential thinkers are Michael Behe (b. 1952) and William Dembski (b. 1960). In Chap. 6 of the *Origin of Species*, Darwin had written: "If it could be demonstrated that any complex organ existed, which could not possibly have been formed by numerous, successive, slight modifications, my theory would absolutely break down." In *Darwin's Black Box*, Behe takes up the challenge, offering an argument that he believes to demonstrate the insufficiency of natural selection. In particular, he argues that many biological structures exhibit "irreducible complexity" (Behe 1996, 39). They are systems whose various parts are so related to one another that the removal of any one of them would make the system inoperable. (Behe's analogy is that of

a simple mousetrap, where the removal of any one of its parts would make it unable to catch mice.) His prime example of an irreducibly complex biological structure is the bacterial flagellum, which acts as a kind of rotary propeller. Because, he argues, such a system could not have been formed by “numerous, successive, slight modifications,” it demonstrates the inadequacy of Darwin’s theory.

William Dembski’s views are less easily summarized, but they have to do with the likelihood that a system exhibiting what he calls “specified complexity” would emerge “by chance.” Dembski’s not unreasonable assumption is that we should reject any hypothesis if, given that hypothesis, the fact to be explained (the *explanandum*) would be exceedingly unlikely. How unlikely? Dembski introduces the idea of a “universal probability bound” (Dembski 2002, 22), which he sets at 1 in 10^{150} . He calculates this figure generously by multiplying an estimate of the number of elementary particles in the universe (10^{80}) by the maximum number of changes which could occur each second (10^{45}) by the age of the universe in seconds (which he estimates very generously as 10^{25}). The actual figures are somewhat arbitrary, but this hardly matters. They indicate the degree of unlikelihood that would render a hypothesis worthy of rejection. Dembski’s second move is more controversial. It is to argue that the likelihood that a system exhibiting specified complexity should emerge by means of any natural process falls below this bound. If this were true, then, Dembski argues, all that remains is “design.”

Divine Animation Theory

It is sometimes suggested that the Catholic Church has distanced itself from creationism by accepting the theory of evolution by natural selection. Attention is drawn, in this context, to Pope John Paul II’s 1997 claim that Darwin’s proposal was to be regarded as “more than a hypothesis” (*plus qu’une hypothèse*). But in fact the only human evolution the Pope was prepared to accept is that of the human body. Repeating a claim made by his predecessor, Pius XII in 1950, he insisted that we must regard human

souls as having been “immediately created by God” (John Paul II et al. 1997: 383). That human souls are immediately created by God is itself a traditional Catholic position: It is found, for instance, in the work of Thomas Aquinas (1225–1274). Indeed, it was in reference to such a view that the term “creationism” was first used. So while in one sense the Pope’s position can be regarded as a form of theistic evolutionism, it is, perhaps, better regarded as a kind of “divine animation” theory.

What relation has the Pope’s view to the scientific theory of evolution? There are those who believe it to be scientifically irrelevant. Gould, for example, regards it as an example of his NOMA principle, which leaves the science intact. In a similar way, Michael Ruse suggests that “if you want evolution plus souls, that is your option, and if you want evolution less souls, that is also your option. Either way, evolution is untouched” (John Paul II et al. 1996, 394). But it is not clear that the Pope’s view is so harmless. Insofar as it concerns human beings, evolutionary theory has never limited itself to an explanation of the origins of the human body. Charles Darwin believed that natural selection could explain not merely our emotional life but also the origins of such key human characteristics as the moral sense. Indeed in *The Descent of Man* (Chap. 4), he rejects the idea that our moral sense is somehow implanted by God, seeing it as an outgrowth of those social instincts that are found in many animals.

Is Darwin’s view consistent with the Pope’s position? Apparently not, for however one may regard the powers of the soul (or the powers to which the soul gives rise), the moral sense is surely one of them. So it seems that a Catholic thinker would be forbidden from following Darwin this far. What has happened here is that the Pope has made evolutionary theory theologically acceptable at the cost of limiting its scope. The direct creation of the human soul by God may not be a miracle, in David Hume’s sense of “a violation of a law of nature.” Indeed it occurs in a regular and law-like manner, following the conception of each human being. But it is an event that cannot be explained without reference

to divine action. (Only God could bring about this change.) If one defines creationism as the view that belief in God's creative activity is incompatible with an entirely natural explanation of the origins of the universe and human beings, then the Catholic Church's position must also be regarded as a form of creationism.

Evaluation

While some forms of creationism describe themselves as "scientific" (indeed as "creation science" or "flood geology"), there is little doubt that what they take to be science is decisively shaped by a prior commitment to religious authority. Young-earth creationists in particular follow a policy that is succinctly summarized in the subtitle of Whitcomb and Morris's book: "the biblical record and its scientific implications." It takes as its starting point an interpretation of the biblical text that is as literal as possible, and accepts only that evidence which is consistent with what the scriptures say. Whitcomb and Morris freely admit that this is what they are doing, but justify their reliance on religious presuppositions by arguing that secular science is equally dependent on dogmatic presuppositions, albeit of a different kind. Intelligent design theory (ID) is less obviously shaped by a commitment to scriptural authority, but it would be fair to say that few scientists who are not already committed to a conservative religious position find its arguments as all convincing. There are secular critics of the neo-Darwinian synthesis, but few of these have been convinced by the ID claim that the evidence demands belief in a designer.

Scientific Criticisms

Not only are creationist beliefs based on religious presuppositions, they also face severe criticism on scientific grounds. Indeed attempts to refute creationism date from the very beginnings of the YEC movement, when in 1925 the German geologist and Catholic priest, Stephan Richarz, published a detailed rebuttal of Price's arguments. Contemporary critics point out that creationists appear to misunderstand the theory of

evolution, suggesting that it claims biological organisms to have arisen "by chance." While this does seem incredible, it is also a misrepresentation of Darwin's central idea. The variations on which natural selection operates may arise from processes that are apparently or even irreducibly random. But this does not mean they are "random" in the sense that all outcomes are equally likely. Even processes that are unpredictable at the level of individual events can be governed by probabilistic laws. In any case, the process by which variations are selected is far from random. It is constrained in a variety of ways, not least by environmental pressures.

The ID argument that some biological structures are "irreducibly complex" is more subtle. But it overlooks the possibility that a structure that was initially merely advantageous (and therefore not necessary at all) might later become essential. As H. Allen Orr writes,

some part (*A*) initially does some job (and not very well, perhaps). Another part (*B*) later gets added because it helps *A*. This new part isn't essential, it merely improves things. But later on, *A* (or something else) may change in such a way that *B* now becomes indispensable. This process continues as further parts get folded into the system. And at the end of the day, many parts may all be required. (Orr 1997)

When sea-creatures first developed lungs, their new organs were merely advantageous. But once their descendents became thoroughly terrestrial, lungs became essential. If processes of this kind lay behind the development of the bacterial flagellum, it is not "irreducibly complex" at all.

Theological Challenges

Whatever one makes of their science, creationists do raise some serious theological questions. Even if something like the theory of evolution by natural selection is compatible with classical theism, in the sense that both could be true, an evolutionary view of human origins offers some challenges to the believer. Firstly, it undercuts what was once a very popular form of argument for the existence of God, the argument from the complexity and adaptation of living organisms.

As Darwin wrote in his autobiography, “the old argument of design in nature . . . fails, now that the law of natural selection has been discovered” (Darwin 1958, 87). Secondly, even if it is *possible* that God created the diversity of living beings by way of natural selection, we can still ask if this is how we would expect an omnipotent and benevolent deity to act. One might argue that the wastefulness and apparent cruelty of the process is evidence against the existence of the God in whom Jews, Christians, and Muslims profess to believe.

With regard to the relation between religion and science, creationists are sometimes accused of a “god of the gaps” theology, in which divine action is posited in order to fill an explanatory lacuna in our existing scientific theories. In doing so, it is said, they offer hostages to fortune, since science may come to offer natural explanations that supplant the theological ones. But it is not clear what force this criticism has. After all, the challenge faced by the theistic evolutionist is that of explanatory redundancy. If “secondary causes” can do all the explanatory work, why bother talking about divine action? The problem was already recognized by Aquinas in his *Summa theologiae* (1a, qu.2, art. 3, obj. 2), who, of course, formulated his arguments for God’s existence in response. It follows that it is not enough to assert the compatibility of evolution with the doctrine of creation; one must give some reason to speak about divine action in the first place.

Young-earth creationists also pose very sharply the question of scriptural authority. Many theistic evolutionists regard Darwinism as incompatible with a literal reading of Genesis 1–3, but reconcile their science and their religion by reinterpreting the biblical account of the creation. But is such a reinterpretation justified? A traditional Christian view of biblical authority, dating back to St Augustine (354–430 CE), offers principles for settling apparent conflicts between divine revelation and secular knowledge. The first of these, which we may call the *principle of the priority of demonstration*, holds that where enquiry based on natural principles leads to a conclusion that both conflicts with a literal reading of Scripture and cannot be doubted,

Scripture must be reinterpreted (McMullin 1998, 294). By way of contrast, a second principle, the *principle of the priority of scripture*, states that when rational enquiry leads to something less than certainty, the authority of the literal sense of scripture is to be preferred (McMullin 1998, 295). Nor are these merely ancient principles. They were employed by the church authorities during the trial of Galileo and invoked by Pope Pius XI in 1950 when condemning polygenism (the view that the human race had more than one origin). It is true that neither Pius nor his successors advocated a literal interpretation of the 6 days of creation. But one can understand why those who hold to a strong view of biblical authority might be reluctant to abandon what they see as the plain sense of God’s word in favor of a “mere” human theory, no matter how well supported that theory may be.

Description

The creative writing program is generally divided into either a Masters of Arts or a Masters of Fine Arts. While either program offers various creative writing courses and workshops, the latter is generally weighted toward almost all writing while the former includes the academia of literature. Many creative writing programs, especially in the United States, prefer a Bachelors degree in either literature or creative writing before entering their program, but it is not always mandatory.

A few institutions, within the last decade, have also been offering a Ph.D. program for creative writing, but it is the exception.

In general, creative writing courses range from online to full-time to bimonthly meetings with advisors. The latter has proven particularly successful because of the freedom it provides for students with full-time jobs and families. It also forfeits the expense of campus living.

Increasingly, universities and colleges have been extending their programs into summer workshops that are usually held in tourist destinations. This allows a participant to feel as if they are on vacation, but also focused on his or her particular writing discipline such as poetry, fiction, and creative nonfiction. The workshops usually include authors of some reputation working and living with the participants.

The academic study of creative writing does not belong specifically to the fields of science or religion, but both studies are an integral and often inspirational part of the creative writing process. While it is too numerous to list the influences of science and religion upon certain works of creative writing, the impact extends well beyond the genre canons of science fiction and Christian or spiritual fiction.

In the last four decades, the amount of creative writing programs in the United States has increased from 37 to 822 while, conversely, the overall sales of books have been steadily decreasing. There have been various theories as to this cause including the loss of the independent book-seller, to cable television, to video games.

The first serious creative writing program is attributed to the Iowa Writers Workshop, set up after World War II as an attraction for those entering the university on the G.I. Bill. While establishing itself as a regional school, the Iowa Writers workshop also included writers from China, South Korea, England, and other countries. Many of the other programs that began in the south, and most recently, in the Western States, have focused on a more traditional regionalism, incorporating local voices more often than international ones.

Within the last 10 years, institutions of higher education have become even more specific in

their focus. For example, The University of Oregon's MFA program encourages the "act of writing," the University of Florida hopes to "produce good writers," and the University of Wyoming on students to get "real-life" writing skills (Kathryn Houghton 2006). Many others have begun to offer a cross-disciplinary curriculum between creative writing, screen writing, poetry, creative nonfiction, and television writing.

There has always been a certain level of controversy over the effectiveness of creative writing programs. As mentioned before, with book sales either stagnant or decreasing, the wide-scale loss of traditional bookstores, a rapidly declining readership, and an increase of other media such as video games, films, and internet, the proliferation of creative writing programs have been called into question. Is the creative writing program still relevant or is it simply a way for educational institutions to make money? While many writers and academics have publicly denounced the intellectual merit of such programs, others have come out in strong support. The New Journalist Tom Wolfe has called creative writing programs "swamps" where "mosquitoes breed" while the novelist M.J. Hyland claimed "that a good teacher, and a good course, can speed up the apprenticeship of a talented writer, and give him good company" (Hyland 2009).

Self-Identification

Science

New forms of writing are currently being developed and improved upon including; graphic novels, interactive storytelling, and hyperfiction (online, hyperlinked), to name a few, all in attempt to develop a new vehicle for fiction as well as to deliver a story succinctly and still aesthetically. While there is still quite a bit of experimental fiction, in terms of style, realism, the most common style of writing today has, to borrow Woods' description, "flattened out" with overuse (James Wood 2008). Realism, Woods adds, is probably one of the least realistic styles, if such a statement can be made.

Creative writing programs such as the one at Brown University have sought to discover new ways to connect the age of technology to fiction while others have worked to bring the sentence into its most evolved state, a way to convey a myriad of thoughts, feelings, etc., in a wholly peripheral manner. In doing so, argue writers such as Tom Wolfe, the story itself has been lost to the author's intensive self-reflection and self-consciousness.

Religion

Religion and spirituality are a fundamental part of the western narrative and the writing process itself.

Characteristics

John Barth in the New York Times article *Writing: Can it Be Taught?* wrote that before creative writing programs writers "authors have acquired their authority in four main ways – first by paying a certain sort of attention to the experience of life as well as merely undergoing it; second, by paying a certain sort of attention to the works of their great and less great predecessors in the medium of the written language, as well as merely reading them; third, by practicing that medium themselves, usually a lot; and forth, by offering their apprentice work for discussion and criticism by one or several of their impassioned peers, or by some experienced hand, or by both." While all four of these examples are still in play, John Barth, a long-time teacher of creative writing, believed that the writing programs in higher education provided a competitive and inspirational atmosphere in which aspiring authors could work productively with peers and mentors. While he did not endorse all programs or teachers, he did say that finding the right place, for the right writer could indeed make a difference. He adds: "Either way, the thing gets learned, all right, and it gets learned, where it does, because it got studied, practiced, and reacted to, in or out of school."

According to a slightly more cynical Louis Menand, creative writing programs "are designed on the theory that students who have never

published a poem can teach other students who have never published a poem how to write a publishable poem” (Louis Menand 2009). Menand himself studied poetry at a writing program and while he claims he’s never published a poem, and admits that: “I stopped writing poetry after I graduated, and I never published a poem – which places me with the majority of people who have take a creative-writing class. . .” he is, however, a regular writer at the New Yorker and has written several well-received books of nonfiction.

Relevance to Science and Religion

Science and religion has always preoccupied the writer’s mind and many creative writing programs today are beginning to incorporate a core-curriculum into the B.A. undergraduate study of writing, seeing that the understanding of science and religion is essential in creating authors who have a broader understanding of the world than simply the specific skills of creative writing.

Science and religion are also two major genres of fiction as well.

Sources of Authority

While there seems to be little question that journalism, visual art, and music have a respectable place in educational institutions, creative writing is still often viewed as a solitary activity requiring more will than skill. But most writers agree that the craftsmanship behind story and novel writing requires more than an understanding of writing or literature. A story or a novel is the complex interplay between voice, character, setting, and words, more specifically the right words. Understanding the effect of one’s writing upon an audience is difficult under solitary conditions and that is where the workshop, an examination of a piece by other readers and writers, comes into play. The creative writing program has supplanted the artist colony in terms of giving the writer interaction and dialogue between artists entrance for beginning as well as allowed writers to work closely with more established writers.

In Joseph Heller’s *Portrait of an Artist As An Old Man*, the narrator, Eugene Pota, a writer who is mostly known for a single book he wrote many years previous (closely based on Heller’s *Catch-22*) gives a lecture at a southern university to creative writing students in which he details the unhappy lives and tragic endings of so many writers. “What then, are the reasons, I have to wonder, that make the biographical information of so many of them a body of literature of despair?” He warns parents that if their children want to become an author that they “must spring into action to save that child. Stop it – if you can.” (Joseph Heller 2000). But in the end, Pota knows that few of the students will listen to his plea. Writing as a career is rarely glamorous, often destructive, rarely satisfying, but those willing to enroll in a creative writing program seem to be growing every year as do the amount of novels being written, he says.

While the very definition of an author comes from “authority,” many writers today focus on the vulnerability of the authorial voice, the loss of readership, and the lack of analysis of the modern world. Many authors consciously deconstruct their own authority by connecting personal life choices to the subject in which they are writing upon. J.M. Coetzee’s novel *Diary of a Bad Year* has three voices speaking concurrently. First the authors written political views, second the authors conversations with his neighbors and friends, and thirdly the neighbors and friends view of J.M. Coetzee. By the end of the novel, the author’s “authority” has all but been compromised.

Ethical Principles

Creative writing seeks to understand what the ethics of a certain society are, why they have been created, and how they affect the human character.

Key Values

The key values of creative writing vary from author to author, lending authenticity to the voice.

Conceptualization

Nature/World

Creative writing would broadly define “nature/world” as a setting or an environment that influences the outcomes of certain choices made by certain characters.

Human

The human and his or her experience is the essence of creative writing.

Life and Death

Life and death are simply a mirror for an author’s audience to put the mortality of the characters into perspective.

Reality

Since a writer’s life is to make the unbelievable believable, reality becomes a distant, unattainable goal. Reality in fiction is only as real as a reflection and the surface upon which it appears.

Knowledge

In good creative writing knowledge is always ambiguous.

Truth

Truth in creative writing is only linked to the strength of the author’s voice.

Perception

The narrator’s point-of-view is the only perception.

Time

Time is linked exclusively to the setting and vice versa.

Consciousness

Once again, consciousness is linked almost exclusively to the narrator.

Creativity

► Imagination

Creator – Co-creator

Barbara Ann Strassberg
Aurora University, Aurora, IL, USA

Philip Hefner, a contemporary Lutheran theologian, focuses on human agency in the postmodern world and on the relationship between science and religion. His theology is hermeneutical, showing that the tradition can be interpreted in constructive ways in any situation as long as religious ideas, doctrines, and dogmas are treated as proposals and not apodictic statements. It offers new ways of thinking about God and Creation in relation to technology, especially as applied to medical practice.

Hefner’s ► *theology* focuses on the human being embedded in nature, society, and culture. Its religious roots are in the Lutheran Evangelical tradition, but modified by a focus more typical of eastern religions. Its theological roots go back to Teilhard de Chardin and Ralph Wendell Burhoe, but also include elements of process theology (the evolutionary process of human becoming), feminist theology (holistic approach), eco-theology (environmental concerns) and, above all, post-modern theology. The emphasis is on the processuality of creation; management of paradoxes; interrelations and interdependency of all systems; systemic feedbacks that inform and

modify the evolutionary process; plurality, complexity, and contingency of occurrences; decentrality of creation; ultimate purpose of wholeness; importance of community and politics; and, importance of human agency and ethics, as expressed by human moral competence and readiness for accountability. The evolutionary perspective is grounded in the natural and social sciences. When it is applied to theology, it allows to interpret the creation as a process of evolution, in which humans actively participate as agents of changes.

Hefner has contributed to the evolution of Christian theology mainly through his interpretation of the changing relationship between religion and science, through his work devoted to the metaphoric and symbolic concept of the *created co-creator* (Hefner 1993), and the application of that concept to the interpretation of nature, human nature, society, and culture. Religion and science are the foci of his work, but other components of culture, such as symbols, rituals, myths, poetry, art, technology, and medical practice, help support his claims about the origins and nature of the co-creator, and the mechanisms and direction of the co-creator's evolution, and his or her participation in the processes of evolution of nature.

Nature is seen as God's greatest project. Everything that exists, including humans, societies, and cultures, is natural and a part of creation. Therefore, theology must focus on nature and become informed by natural sciences. Questions such as What does it mean for nature to be part of God's image, and Christ's redemption need to be addressed? If nature cannot proceed adequately without enhancement by human decisions, by what values should those decisions be guided?

Hefner coined the concept of *created co-creator* in the 1980s to refer to the human being as created by God but also shaped by the genetic makeup and culture that have emerged in the ongoing process of nature's evolution. Since human genetic and cultural makeup keeps changing, being a human actually means participating in a process of becoming human. The human purpose is to contribute to the wholesomeness of natural processes, and the meaning-creating

activity grounded in the functioning of our minds is our most important activity. Our activities and their outcomes (e.g., cloning, genetic engineering, creating transhumans) become consistent with nature and, thus, with God's Creation. Through imagination, humans create the future, and whatever they create are natural, "quintessential human acts" (Hefner 1998). Hefner asks: What is this biocultural human being created for? What forms can this symbol take? What is the significance of cloning as revelation of the human situation? Is genetic engineering now an integral element in human nature? Is this ability now a defining mark of what it means for us to be human? If we consider human life to be sacred, can genetic alteration be included in our concepts of the sacred? (Hefner 2007)

Hefner further claims that *society*, as an outcome of the evolutionary process, should be considered by theology informed by social sciences. The survival of societies depends on what is being done to the techno-earth – the ecosystem transformed by technology. Nature technologized by humans allows technological civilizations to emerge. It comprises social systems that interact with the ecosystem transformed by the created co-creator.

Culture is also an extremely important outcome of the evolutionary process in Hefner's theology. "Culture is where it happens" – he claims. Societies create cultures and cultures shape societies. But above all, the work of the created co-creator happens in culture. That work is guided by values, myths, narratives, symbols and rituals, and the politics of symbols and rituals that shape the praxis for the support of the earth. Among the many elements of culture, Hefner selects *religion and science* for a more detailed scrutiny.

Hefner starts with a dialogical model of the interaction between theology and science, but evolves toward a model of the wholeness of *religion-and-science*, as one compound noun, a symbol of the human quest for meaning. He wants the yoking of science and religion to be translated into policies and practices that contribute to human welfare and the good of the planet

(Hefner 2005, 2008a, c). He switches from a focus on theoretical science to one on scientifically informed technology, as well as medical and technological practice. Science and religion are contextualized by social institutions and intertwined with all other elements of culture before they manifest themselves in the complex human experience. Myths that societies create and tell are one example of an important factor influencing both religion and science as if from the outside at any point in time. According to Hefner, much work has been done to illustrate how natural and social sciences inform theology, but much less has been done to show how theological interpretations of religion may inform natural or social sciences. Even less has been done to define the role of religion for science and technology (Hefner 2008b). Therefore, he suggests that religion can play a reflective, defensive, practical-moral, and spiritual role. This leads him to ask such questions as: What difference would the fuller expression of religion make to science-religion interaction? What is the source of *creativity* and power from which a self-generating nature emerges, beginning with the Big Bang and the Primal Soup, and continuing in our time with the self-conscious human techno-creator? How should we address the question of accountability for the co-creation? Why is it important to recognize the mythic undercurrent in scientific and technological endeavor?

► *Technology*, according to Hefner (2003a), is embodied science. It is not only full of religious meaning, but it is a sacred space where God engages us in a creative confrontation. Technology combined with engineering creates the technological civilization, which makes us dependent on technology in utterly new ways. Now we are capable of constructing cyborgs and transhumans, that is, technologically enhanced and genetically engineered humans whose mental and physical abilities and aptitudes have been altered by our will (Hefner 2003b, 2008d). These new forms of life break down the boundaries between nature and humans, culture and nature, humans and animals, nature and technology, physical and nonphysical. In Hefner's

interpretation, such boundaries have been artificially constructed and imposed, although there is continuity between nature, humans, society, culture, and technology. Cyborgs and transhumans are simply the newest outcomes of the process of nature's evolution. Thus, Hefner asks: How can our traditional ideas of God, creation, and nature be reformulated, so as to be able to interpret cyborg/created co-creator? What shape can moral theology take so as to speak of and to a cyborg/created co-creator? Where is the boundary between healing and improvement or enhancement? What is our improvement or enhancement for? Finally, in his most current writings, Hefner devotes a lot of attention to medical technology and claims that the central issue is "the insistence that our original nature, received in conception and birth, is open to alteration at our own hands" (Hefner 2008d). He asks: Toward what project does our intentionality aim? How far can we extend the right to be healed? How do we approach the issue of justice in this realm? Hefner's theology is evolutionary, visionary, flexible, and adaptable to the future, continuously imagined, and constructed by the *co-creator*.

Credition, the Process of Belief

Hans-Ferdinand Angel
Faculty of Catholic Theology, Karl-Franzens
University, Graz, Austria

Related Terms

Process of believing

The term “credition” is a neologism, which is conceived in analogy to emotion and cognition and denotes the process of believing as it appears in religious as well as in nonreligious contexts (Angel et al. 2006). In common understanding believing is mainly related to religion. That is the case especially in the Western – and partly the Slavic and Middle Eastern – sphere, where the notion of religion is usually associated with the so-called Abrahamic religions (Judaism, Christianity, and Islam). In the Western tradition, an explicit or implicit focus on the concept of religion frequently has prevailed since earlier philosophical debates. For instance, scholars have reflected the relation between religion and science (Gutting 1983; Brooke 1991), between belief and knowledge (Polkinghorne 1998), or

between “fides et ratio” (Plantinga and Woltersdorff 1983; Helm 1999). Philosophers of religion have come to make a distinction between faith and belief (Swineburne 2005; Smith 1998; Kenny 1992; Sessions 1994; Mitchell 1994) [see article on “► Faith and Belief” by Taede Smedes in this encyclopedia]. But, indeed, many of the current academic discussions concerned with the character of believing attempt to ignore the religious fixation (Stich 1996; Boyer 2002, 2003). This reveals a problematic trace in the European history of mind which is characterized as preferring a far too exclusive fixation on religion and neglecting “religiosity” as a highly relevant anthropological approach to understand human beings and their behavior [see article on “► Religiosity” by Hans-Ferdinand Angel in this encyclopedia].

As a theoretical construct, the concept of credition focuses on the process character, that is, on what happens “while someone is believing,” rather than on the relationship between belief and knowledge or “fides et ratio.” Creditions are related to cognition and emotions to which they stand in a finely tuned balance. Hence they are connected with empathy, perception, action control, memory, and the self-concept. Creditions are conceived as mental processes which are thought to have an important impact on (the control of) human behavior. Neuroimaging and neurophysiological studies have shown that belief processes involve brain areas known to be involved in emotion-related and cognitive processing. But there is a discrepancy between the increasing interest in empirical research and the lack of coherent terminology and conceptualization which might be bridged by the concept of credition (Seitz and Angel 2012). The term credition can be conceived on the one hand as a psychological concept (Angel 2011), and on the other hand it can also be held up as a philosophical concept, more precisely, as one of the philosophies of mind or even of *philosophies of mind in process* (Angel 2012). Accordingly, questions like those of degrees of belief (Huber and Schmidt-Petri 2009), the role of (subdoxastic) will

(resp. volition), intention, desire, passion, or justification and morality can be raised.

Processes of believing, one the one side, are results of attitudes. One the other hand, they influence them as well as they influence our actions. Creditions as mental processes are conceptualized at the interface of perception and action. They may be understood as a kind of operator, which is involved in the manifold processes between a perception-related input and an action-related output. Subjective appraisal plays a dominant role for valuation of internal and external events as well as in subjective control of action (Seitz et al. 2009). Its driving forces are part of processes which are commonly ascribed to religious or secular beliefs.

Creditions are proposed to be characterized by four interdependent biopsychological functions: the enclosure function, the converter function, the stabilizing function, and the modulator function (Angel 2011). Recent neuroimaging and neurophysiological evidences suggest that the model of creditions may be justifiable from a neurophysiological point of view in as much as certain cerebral processes appear to be compatible with the concept of creditions. Specifically, cognition-based perspective taking and emotion-based perspective taking engage different closely adjacent, but functionally different nodes within large-scale cerebral circuits involving the medial frontal cortex" (Seitz and Angel 2012).

Function of Credition

1. The enclosure function

This function is a cognitive process constituting or modifying "bab-configurations," which can be understood as *emotionally shaped propositions*, such as vague ideas, confirmed knowledge, values, moral claims, and intuitions. In this sense, bab-configurations are those subsets of *mind-sets*, which are activated when a process of believing starts. Any vague or doubtful (acoustical, optic, olfactory, sensual) perception of an external or even of an internal event can be understood as a "bab," which may be included

or excluded into someone's bab-configuration. If someone does not trust the quality of drinkable water offered in a glass, the qualification "drinkable" might become a "bab." It is due to the enclosure function whether this "bab" will be enclosed into the bab-configuration of the agent. If it is to enclose then the action will be directed toward "drinking," and if it is not to enclose it is unlikely that the water will be consumed. Notably, it is not presupposed, that all processes of believing reach consciousness (Wegner 2002; Teske 2007). In order to accommodate subliminal processes (or even subliminal persuasion) "nonconscious babs" were designated as blobs which, nevertheless, are effective by influencing affects, motivation as well as actions. The nonconscious existence of an exaggerated hygienic "worriedness" (concern) might function as blob in a bab-configuration. As a result its influence onto the enclosure process will lead to the exclusion of the bab "drinkable" – with further result, that the agent will refuse to drink the offered water. Furthermore bab-blob-configurations are characterized by babs/bobs of different "mightiness" (e.g., mini-babs or mega-babs), which means that in a bab-blob-configuration of identical propositions big differences might exist according to the "mightiness" of the enclosed babs/blobs. As every single bab (and blob) is not fully conceived without its (generally changeable) emotional loading also the interrelations between the babs/blobs within a bab-blob-configuration are not to be understood without affects and emotions, and their relation might be expressed in terms of statistics.

2. The converter function

The second function of creditions is activated when bab-configurations are transformed in action. For example, when in a given bab-configuration of an agent exists the bab "cats are divine animals," then in case of a fire, the agent will be prepared to rescue the cat from the fire first. This preparation process is interdependent with several systems, as for instance the predictive system which provides the individual with information about the feasibility of deployable actions and, in consequence, modulates the

preparation of actions (Delevoeye-Turrell et al. 2010). The impulses coming from the bab-configuration will not provoke single acts: rather, the converter function is preliminary to the concrete act sketching out a *space of action*. The term space of action is introduced to mark a middle stage between motivation (cats are divine animals) and action (rescue the cat). Creditions support via the converter function the preparation of actions by reducing the number of choices and abbreviating the time of decision-making. This transformation is complex and all the problems discussed in theory of mind might be relevant for this concept.

3. The stabilizer function

While the enclosure process has the function to produce bab-configurations, the stabilizer process has the function to maintain them. The stabilizer function calms the bab-configurations, which are continuously modified by new experiences of the subject, and reduces the volatility of irritating impulses, which are sent by the enclosure process to the converter function. Therefore, the stabilization of bab-configurations is an inevitable precondition for consistent “spaces of action.” The stabilizer function brings creditions into touch with attitudes and mind-sets. Many complex challenges of everyday life, as for instance decision-making, planning, or (re-) building of trust, are only possible on the basis of a coherently shaped space of action. Most likely these functions are implemented on different stabilized neural circuits.

4. The modulator function

This function of credition highlights in a specific way the differences of individuals and the differences of situations, in which a creditive process can occur. Obviously, creditions are interrelated with the individual’s body, his or her memory, gender, health, disability, or psychic integrity. They are bound to the individual state of cognitive and/or emotional development, be it conscious or nonconscious. When regarding the modulation function on the levels of cells, for example, we might see the influence of neural synchronizing processes. On the other hand, the course of creditive processes might be modulated

by actual bodily states as stress, loss of trust, arches and pains, sadness, or sexual arousal. It is an intriguing perspective in which way emotions and appraisal influence the modulation of creditions. In addition: It may be discussed whether the modulator function should be regarded more as a general principle that influences the three other functions in a specific mode.

Since creditions are purely mental processes, they will follow their specific courses independently from outside influences, which, nevertheless, will influence the contents of these processes. This kind of learning is not specific to religious beliefs, but might in a comparable way also occur in secular belief processes such as in faiths or in social or moral convictions. Therefore, creditions play a role not only in interreligious dialogues, but also in politics, economy, education, human rights, minority protection, or anti-discrimination. They are relevant to understand the diversity of man on the one side and similarity on the other. As a process-orientated approach to faith, to trust, and to belief the concept of credition may integrate divergent philosophical, psychological, neurophysiological, and other conceptual aspects. It can be used as a starting point for further interdisciplinary research questions and be fruitful for the discussions described above as for many others.

Criminology

Patricia E. Erickson

Department of Sociology, Anthropology, and Criminal Justice, Canisius College OM-016 C, Buffalo, NY, USA

Description

Criminology is an academic discipline devoted to the scientific study of crime and criminal behavior. Although contemporary criminology is multidisciplinary, encompassing a variety of fields such as anthropology, biology, economics, law, political science, psychiatry, and psychology, the sociological approach to criminology is especially dominant. While the central focus of criminology is to examine the causes and consequences of crime and criminal behavior, contemporary criminology also contains a number of other subareas of inquiry. The sociology of law is a subarea concerned with the role of social forces in the creation, modification, and application of laws. The specialty area of criminal statistics and crime measurement focuses on developing reliable measures of criminal activity. Victimology is a specialty area concerned with the role of the victim in the criminal process, and especially how society responds to the needs of victims. Finally, criminologists are also involved in examining social control mechanisms in society; penology is the study of the punishment and treatment of criminal offenders. Recent developments in criminology concern the development of new criminological perspectives that

challenge the assumptions of traditional criminology. Often these perspectives are postmodern approaches that reject scientific rationality as the method for studying crime and criminal behavior. The emphasis of postmodern approaches is to “deconstruct” assumptions of traditional criminology. Some approaches offer humane alternatives to traditional methods of crime control. Restorative justice, for example, focuses on the needs of the victim, offender, and the community by emphasizing remedies and victim/offender reconciliation rather than offender punishment and victim neglect.

Self-Identification

Science

Contemporary criminology self-identifies as a science. Its emphasis is on empirical research and scientific methodology. However, in its early development in the mid-eighteenth century, criminology was not grounded in science but rather in social philosophy. Known as the classical school of criminology and based on utilitarian principles, the classical school asserted that individuals have free will to make their own choices to act, that decisions are rationally made based upon seeking pleasure and avoiding pain, and that the role of punishment is to deter criminal behavior. The use of scientific method to study crime and criminal behavior developed in the late nineteenth century with the emergence of the positive school of criminology. The positive school attributed internal and external influences outside of the individual’s control as the cause of criminal behavior. Positivists assumed that behavior is both determined and measurable and offered biological, psychological, and sociological explanations as the causes of criminal behavior. In the twentieth century, sociological positivism became the central scientific explanation of crime and criminal behavior and the primacy of sociological explanations continues today. Sociological criminology contains a number of theories of crime causation, but traditionally, sociological criminology is divided into explanations which are social structural as contrasted

with explanations which emphasize social interaction. Sociological criminologists use both quantitative and qualitative methodologies, although quantitative methods provide the primary research approach.

Characteristics

There is a related discipline of criminal justice which is also concerned with crime and criminal behavior. However, the study of criminal justice concerns the system of law that is directly involved in the apprehension, prosecution, defense, sentencing, incarceration, and supervision of those suspected of or charged with criminal offenses.

Relevance to Science and Religion

Criminology examines the role of religion in criminal behavior. Criminological theories identify the basis for hypothesizing a negative relationship between religion and law violation. Criminological research generally identifies religion as an independent variable with variations in criminal behavior as the dependent variable. This research indicates, for the most part, that religious beliefs and activities are negatively related to violating the criminal laws of society. However, criminological research also recognizes that religious extremism can provide motivation and support for criminal behavior by misusing religion to justify criminal acts.

Criminologists also investigate the positive role of religion in rehabilitation and treatment programs, focusing on religious practices among prisoners. Finally, criminologists also recognize the biblical basis for the restorative justice approach in criminology.

Sources of Authority

Criminologists submit both theoretical papers and empirically based research papers to

peer-reviewed journals in their discipline where the papers are subject to blind review. In addition, professional organizations such as the American Society of Criminology recognize outstanding scholarly contributions to the discipline.

Ethical Principles

The ethical principles that guide criminologists concern research ethics. Criminologists are obligated to report all sources of financial support and other sponsorship of research. Ethical principles also require the full reporting of research findings and fully recognizing the contributions of colleagues. In addition, criminologists also have ethical responsibilities concerning research subjects. They are obligated to ensure that the physical, social, and psychological well-being of an individual participating in research is not adversely affected by participation in the research, and they must protect the privacy of human subjects and confidentiality of the data collected.

Key Values

Criminologists value the advancement of knowledge about crime and criminal behavior. They are committed to the free and open access to knowledge and to public discussion of findings. They value objectivity and professional integrity in performing and reporting research. While values regarding science and scholarship predominate, criminologists are also concerned with the application of their findings. Social policies concerning crime and criminal behavior should be linked to findings of sound criminological research.

Conceptualization

Nature/World

The world is conceptualized as human society and human society is a socializing/civilizing agent.

Human Being

Human beings are social as well as biological beings. Both internal (biological, psychological) and external (social) factors explain human behavior.

Life and Death

Criminologists focus on social life – life after birth and before death. There is no specific conceptualization of the origins of life or the meaning of death.

Reality

Criminology conceptualizes reality in terms of the norms, customs, values, and ideologies of a society. Its focus is on the social reality created by human beings through social interaction.

Knowledge

For traditional criminology, knowledge is the result of the scientific and empirical study of social reality. For postmodern criminology, knowledge derived from the scientific and empirical study of social reality is only one way of knowing; there are a number of equally valid ways of knowing.

Truth

Truth in traditional criminology would be the ability to use the scientific method to understand crime and criminal behavior with certainty which is not possible. Criminology has an empirically based but imperfect understanding of crime and criminal behavior. In addition, postmodern criminology would challenge the assumption that it is possible to reach an objective truth concerning crime and criminal behavior.

Perception

Perception is a research variable. Criminologists examine the role of perception in crime and criminal behavior.

Time

Time is considered a dimension for measuring changes in societal definitions of crime and criminal behavior. Time is also a dimension used for

determining how long an individual may be held liable for a criminal offense (statute of limitations) and how long an individual may be punished for an offense.

Consciousness

In order to be held criminally responsible for committing crimes, individuals must be conscious of their actions. The elements of a crime are *mens rea* (guilty mind/criminal intent) and *actus reus* (wrongful act). While a limited number of offenses are strict liability offenses and only require the *actus reus*, most crimes require both *mens rea* and *actus reus*.

Rationality/Reason

Reason/rationality is important in criminology for two reasons. First, it forms the basis for scientific positivism and therefore it forms the basis for knowledge in traditional criminology. Second, classical criminology and rational choice theory, the modern-day version of classical theory, holds that criminality is the result of conscious choice and predicts that individuals choose to commit crime when the benefits outweigh the costs of disobeying the law.

Mystery

Mystery is not a concept that appears in criminological literature; it does not appear in criminological theory and it is not a variable in criminological research.

Relevant Themes

It is important to recognize that criminology consists of many theories of crime causation. Typically these theories emphasize empirical research and scientific methodology and posit either biological, psychological, or sociological explanations. Sociological theories predominate and generally are classified as (1) social structure theories, (2) social interaction theories, or (3) social conflict theories. Postmodern criminology challenges the assumptions of traditional criminology.

Criteriologic Problem

Olof Franck

Department of Pedagogical, Curricular and Professional Studies, University of Gothenburg, Gothenburg, Sweden

The idea of a criteriologic problem generates from what seems to be an indisputable fact, namely, that religious sentences are criteriologically problematic in that there does not seem to be any ordinary method by which they could be shown to be true or false. By an "ordinary" method is meant one that in some way relies on empirical standards, and since the central sentences belonging to religious traditions and systems of belief would seem to be interpreted as aiming to say something about a nonempirical object, the conclusion is drawn

that the sentences are problematic from a criteriologic point of view.

Of course, some of the sentences used and uttered in religious contexts, such as perhaps historical ones about the birth, the life, and the death of such important leaders as Siddhartha Gautama, Jesus Christ, or Mohammad, could, at least in principle, be tested by ordinary empirical and scientific methods. But the central sentences in various religious traditions, for example, “God loves all people” or “The goal of reincarnative existence is moksha,” do not rely on empirical references. Let us call such sentences “belief sentences”! The criteriologic problem, then, could be said to arise from the supposed fact that there seems to be no ordinary method by which belief sentences could be shown to be true or false.

The crucial question, though, could be said to be one that sets focus upon what is to be judged as a “criteriologically problematic” sentence. Which standards could be used, and are there standards with universal extension? Could sentences from one context, such as religion, be evaluated and tested by the same criteria that are used in another, such as science or everyday life?

In modern ► [analytical philosophy of religion](#), a great deal of the discussion on the criteriologic problem has started in a verificationist interpretation of it, which, in its turn, falls back to the Vienna Circle and the antimetaphysical logical empiricism of the 1920s. The logical empiricists set up strictly formulated criteria to differentiate between “meaningful” and “meaningless” sentences. These criteria were built around the concept of empirical observation, initially expressed in terms of conclusive verification, but later on in milder versions, verificative and falsificative. The basic idea for the logical empiricists was that meaningful sentences, with some empirical method, at least in principle, could be shown to have a truth-value. Since what we have called “belief sentences” were judged to fail to pass this test, they, together with other metaphysical sentences, were doomed to lack meaning and, consequently, truth-value (Diamond and Litzenburg 1975).

Despite the philosophical death of logical empiricism, the demand for empirical verificative or falsificative tests to ensure the possible truth-value of sentences has continued to live a rather vivid life, not the least in the field of philosophy of religion. Even if the standards of meaningfulness formulated by the logical empiricists showed to be all too rigid and untenable, the basic idea that there has to be some usable method by which belief sentences can be sanctioned “true” or “false,” if these sentences could be said to be relevant for the empirical world and the lives of its human beings, has survived.

The main line of divergence in relation to this demand, at least in the 1950s and the following decades, can be identified to separate reformative verificationist approaches from a Wittgensteinian one, according to which belief sentences have their own standards of meaning and truth found in the religious contexts or, using the terminology of Wittgenstein, “language games,” where they are used, and that there consequently does not exist a “criteriologic problem.” Such a problem presupposes that there are general, and perhaps universal, standards of comprehending and testing sentences from all kinds of contexts of human life, but since there are no such standards, there is not any problem of a “criteriologic” kind. Language is a matter of pluralism concerning uses and rules and meanings, and to raise any universal demands in order to obtain non-pluralistic expressions of meaning and truth is doomed to fail (Wittgenstein 1978).

This is, of course, a response which, at its fundamental level, few today would oppose to. The pluralism of language, the differences between various areas of human enterprises and domains of life, and the many-faced picture of methods and criteria to be used to interpret and test the semantic expressions of those differentiated contexts – nothing of this seems to be all too surprising or, for that matter, problematic to anyone familiar with the philosophical discussion related to semantic and epistemological topics today. After the postmodern era, with its criticism of traditional ideologies and religions and its rejection of universal standards for applications of presumably homogeneous concepts such as

“meaning” and “truth,” the aim to find definite criteria in order to separate “meaningful” sentences from “meaningless” may seem to be a project of a strictly historic interest.

The question, then, is if the criteriologic problem is to be judged as one of those “obsolete” obstacles from the history of philosophy. Is the demand for usable criteria in order to test the actual or possible truth or falsity of belief sentences to be declared misguided and, perhaps, unreasonable?

There are, at least, two reasons why the suggested lack of a definite method for testing the truth and falsity of belief sentences would seem to be of a more profound interest than being reduced to a historic parenthesis. First, the basic idea that sentences that seem to propose or state something about an existent reality, if such a proposal or statement is to be in any way relevant to people living their lives in relation to this reality, is in itself independent of specific methodological constructions, like the verificationist ones. Even if all methods hitherto presented have shown to be misguided or unreasonable, this fact would not constitute a conclusive reason to negate the demand for criteria which could be used to judge belief sentences as “true” or “false.” Second, the global world, with its increasing space of communication across not only geographical but also cultural and religious frontiers, actualizes the question in which respect it is possible to keep an epistemological dialogue concerning disparate religious claims alive. When people representing different religions and traditions come together debating questions touching about all kinds of subjects where claims of truth are presented with reference to religious authorities of various forms, the question how it would be possible to settle disputes concerning reasons for and reasons against those claims respectively arises. Are such disputes really to be left without at least a try to – by some attended criteria – solve them, not perhaps definitely, but through handling them, perhaps in terms of some probability calculation or at least some evaluative procedure of an epistemologically relevant kind?

Commenting first on the initial reason mentioned, one could elaborate a philosophical

perspective which sets focus upon the epistemological question why religious people seem to be anxious to talk about their beliefs in terms of “truth” while, at the same time, they seldom express the same kind of anxiety for the project to show in accordance with which criteria their belief sentences could be established as “true.” Looking back through the decades where the criteriologic problem has been discussed, believers generally seem to have been rather uninterested in taking part in the discussion. The demand for a criteriologically satisfying method for testing religious sentences was of a philosophic kind, and perhaps its relevance for practicing believers did not become clear. Why bother about philosophical criteria of truth when the presence of truth in the personal belief is experienced as so vivid and so lively? Even the most debated criteriologic challenge during the decades after the 1950s, namely, the one formulated by the British philosopher Antony Flew, then probably one of the most well-known critics of religious truth claims, seems to have been most reflected, not by religious believers but by philosophers of religions which aimed to formulate a theoretic response to meet the challenge. According to Flew, building his argument around a falsificative criterion of meaning, believers faced with evil in the world still continue to hold on to sentences about “God’s existence” and “God’s love” even though there is so much that would count against the truth of these sentences. If the sentences had a definite meaning, they would have been accepted as falsified: an existing and loving God would not allow all the pain that people are forced to experience in life. But believers refuse to accept this: instead, they keep their belief in the truth in the sentences and thereby, Flew states, make the claims of them compatible with anything that would happen – that is, they make them say nothing of relevance to the empirical world since not anything in this world is allowed to count against their truth (Flew 1966).

Many philosophers of religion have tried to meet this challenge by formulating criteria which would save the empirical relevance of the sentences, sometimes in terms of verificationist

fundamentals and sometimes in other ways, for example, John Hick and Basil Mitchell, respectively, just to mention two examples. Common to them all is that they accept the challenge of Flew as a real challenge and that the criteriologic problem really is a problem to be handled and taken care of. Even though none of these philosophic responses have shown to be overwhelmingly convincing, they can be considered as serious efforts to develop a line of argumentation for how belief sentences, in spite of their nonempirical character, could be established as relevant to people who live their lives in the empirical world. In some way, these efforts can be interpreted as projects where tools to make the nonempirical relevant to the empirical, and vice versa, are being looked for and elaborated (Franck 1988).

As to the second reason mentioned above, why the criteriologic problem should not be considered as a strictly historic one, here it also has to be pointed out that the multicultural and multireligious communications in today's world make it interesting to reflect upon the epistemological presuppositions and consequences of intercultural and interreligious dialogue. When, for example, conservative believers in the name of some religious authority or according to some interpretation of a supposed holy book argue against the democratic rights of women or homosexuals or propose that creationism is a theory which ought to be taught in school alongside evolutionary theory and when liberal believers together with nonbelievers oppose to these claims, does it not seem clear that a refreshing investigation of the criteria for proposing belief sentences as "true," at some point in the discussion, has to be performed? The criteriologic problem seems here to be most vivid and demanding. Is it possible to claim that "God forbids women to live in exactly the way that men do" or that "God opposes to every kind of sexual activity except for those that are of a heterosexual kind" express "true" sentences? It seems to be reasonable to meet such claims with the standard epistemological question: "How do you know that?" And when this question is posed, the criteriologic problem has been semantically incarnated once again.

The challenge which the criteriologic problem poses is, however, today one is seldom met by projects where one tries to establish a more precise methodological standard in order to evaluate the truth-value of this or that belief sentence. Rather, today's colleagues of the philosophers of religion of the last decades of the twentieth century, generally speaking, are more interested in interpreting, analyzing, and, when this is thought possible, classifying the central beliefs of different religious traditions and the semantic expressions of them, in terms of the realist–non-realist distinction. One of these colleagues is the Swedish philosopher of religion Eberhard Herrmann, who has dedicated a great deal of his latest work to an analysis of questions related to this perspective (Herrmann 2004). The focus has shifted from penetrating the question how verificative or falsificative criteria could be found to anchor a satisfying test of belief sentences to a dedication to relating the fundamentals of religious belief to a perspective where questions concerning meaning and reference are put in the center. Here, the project is managed within a broad frame of reference to philosophical theories and positions: the criteriologic problem is not seen as especially unique to religious contexts; rather, it is one instance among many when it comes to the question how language, religious or nonreligious, could be interpreted in relation to semantical, epistemological, and ontological criteria of meaning and truth.

The criteriologic problem, then, is still alive and continues to attract an important interest, but the ways of trying to come to terms with it have changed. When belief sentences from a religious point of view is said to be "true," the question "How do you know?" is, of course, relevant today precisely as it has been for all times. Philosophers of religion in our days do, however, seldom take part in enterprises where specified verificative or falsificative criteria are tried to be constructed. Rather, they choose to analyze the language of religions in terms of realist or non-realist theory and try to investigate how different philosophical theories on truth conditions could be applied to religious sentences such as belief sentences.

Critical and Cultural Theory

Eduardo Maura

Facultad de Filosofía, Universidad Complutense de Madrid (Spain), Madrid, Spain

Related Terms

[Critical theory](#); [Critique of enlightenment](#); [Critique of reason](#); [Culture theory](#); [Frankfurt school](#)

The term “critical theory,” due to its inner ambiguity, is to be understood in two senses. In a broad sense, it covers those disciplines within the social sciences, which offer a critical account of society, knowledge, and culture (including political systems, arts, and literature, among others). Since the 1970s, reacting to New Criticism in literary theory, these disciplines have overlapped, particularly in the English-speaking world, leading to a broader paradigm of criticism. On this basis, the definition of critical theory includes queer theory, the theory of communicative action by Jürgen Habermas, feminist theory, critical legal theory, psychoanalysis, neo-Marxian theories, and many others.

In a narrow sense, “critical theory” refers to different generations of the Frankfurt School and, in general terms, not only to the members or followers of its circle but also to its surroundings. Given that the Frankfurt School has been traditionally recognized as the most influential source of critical social sciences – and critical theory of society, in any sense – this entry will mostly refer to it. The work of Frankfurt School writers and researchers develops around the Institute of Social Research (*Institut für Sozialforschung*) in Frankfurt am Main (Germany) and seeks to adapt Marxist theoretical and practical tools in order to analyze twentieth-century capitalist societies. This includes political, economical, and social evolution. The institute was created in 1923 by relevant researchers, such as Felix Weil (1898–1975), Kurt Albert Gerlach (1886–1922), Friedrich Pollock (1894–1970), Karl August Wittfogel (1896–1988), and Carl Grünberg (1861–1940). After a short period of economical and social studies, Max Horkheimer (1895–1973) takes the lead, breaking ground for a new project and becoming representative of the group. He also helped to create the official publication of the institute, the well-known *Review of Social Research* (*Zeitschrift für Sozialforschung*). In the next years, several authors would publish their work on it, including Leo Lowenthal (1900–1993), Theodor W. Adorno (1903–1969), Walter Benjamin (1892–1940), Herbert Marcuse (1898–1979), and Erich Fromm (1900–1980).

From a highly interdisciplinary approach, the school elaborated a materialist social theory, capable of recovering the value of emancipation and transformation of society through the analysis of different forms of domination in advanced societies. With the rise of Adolf Hitler and National Socialism, the institute disbanded, and many of its members were forced to exile, were captured, or even murdered. Particularly relevant during this period of exile was the USA where Adorno and Horkheimer stayed until the 1950s, when they returned to Germany and kept on with the activities of the institute. The influence and powerful attraction of the Institute of Social Research has been proved by the extraordinary emergence of thinkers and researchers over the last 40 years, including Axel Honneth (b. 1949), Claus Offe (b. 1940), Oskar Negt (b. 1934), Alfred Schmidt (b. 1939), Albrecht Wellmer (b. 1933), and Jürgen Habermas (n. 1929), who ranks as one of the most prolific and influential philosophers of his generation.

The questioning about religion as critique has been important in two different senses: Firstly, an increasing number of critical theorists (in the broadest possible sense) have looked for Theology as a likely way out of its own antinomies – the impossibility of thinking under the constraints of global markets and massive cultural industries. Secondly, critical theory has recognized but also diminished the theological field at the same time. That is to say, it has rediscovered its critical value once immersed in a fully secularized world. Like art, religion knows both sides of modern societies: (1) its scope is wider than those of natural and social sciences, and (2) pays increasing attention to social pathologies. The recent debates between Jürgen Habermas and Pope Benedict XVI (then Joseph Alois Ratzinger) have focused on the role of reason and religion in a free society.

Springing from the Marxist diagnosis on modernity and its unsolved problems, critical theory is to be originally understood as a theoretical fight against ideologies, serfdom, and domination, and also as a quest for a critical use of reason and emancipation. But what Horkheimer and the others undertook was

also a profound revision of basic principles of traditional Marxist theories: social evolutionism, lack of attention to ideological and cultural details of domination, and the controversial Marxist faith in the working class (*das Proletariat*) as the historical subject of social change. Opposite to this, critical theory recovers a dialectical comprehension of society and links theoretical, critical, and practical uses of human reason. Thus, critical theory makes up an emphatic concept of social reason far beyond merely methodical or scientific uses of rational faculties and, therefore, relives its practical power – then again, named as critical autonomy or suppression of the sphere of domination. They argue that technical and scientific outcome from social reasoning (certainty of the relationship with nature, increase of welfare) must add to the political overturning of conditions of social irrationality in order to establish a rational fair order of things. From the beginning, the Institute of Social Research tries to clarify the reasons why Enlightenment has not fulfilled its moral content, paying special attention to bourgeois societies and their mechanisms for socializing and appropriate driving of social response.

When this line of thought becomes central, the Frankfurt School spreads social and cultural criticism to the realm of foundations of reason and mechanisms of thought, adding to critical theory of society and economy a deep analysis of different forms of rationality, speech, and experience. According to this, the traditional model of *critique of ideologies* – the process according to which knowledge of unfairness unmasks false consciousness – is surpassed by *critique of reason* – yet to be understood as the report of those limitations which reason finds when attempting to deny current social conditions. Therefore, critical theory remains aware of its social function and finds itself apparently open to social change. This is where Horkheimer arrives when stating his highly influential distinction between *traditional theory* and *critical theory* (“Traditionelle und kritische Theorie,” 1937). In this writing, Horkheimer deploys the term *traditional theory* to designate classical theoretical models, at least

since Descartes, which look for constant relations between objects – those that can imply technical involvement with reality – and attach to restrictive methodological and analytical procedures. Traditional theory distinguishes itself from other theories for a rampant reductionism that restricts processes of knowledge by avoiding value-instances and inner bounds between objects and their historical and social frame. It is precisely in this way – according to Horkheimer – how sociology confronts its objects as something to be figured out and then commanded. It confines itself to success in prediction. But, as Horkheimer notes, “there is likewise no theory of society, even that of the sociologists concerned with general laws, that does not contain political motivations; and the truth of these must be decided not in supposedly neutral reflection but in personal thought and action, in concrete historical activity” (Horkheimer 1982b, p. 222). If *traditional theory* seeks to put reality in order and build up a permanent notion of truth, critical theory is aware of the relationship between human sciences, interest, and social procedures. Therefore, it makes social change an inner goal: “For all its insight into the individual steps in social change and for all the agreement of its elements with the most advanced traditional theories, critical theory has no specific influence on its side, except concern for the abolition of social injustice. This negative formulation, if we wish to express it abstractly, is the materialist content of the idealist concept of reason” (Horkheimer 1982b, p. 242).

The gathering of thinking and acting, knowledge and praxis, puts critical theory against Max Weber’s notion of value-neutral sociology for it would allegedly conceal the problem of its social position from concrete theoretical work: “Beyond doubt, such work is a moment in the continuous transformation and development of the material foundations of that society. But the conception of theory was absolutized, as though it were grounded in the inner nature of knowledge as such or justified in some other ahistorical way, and thus it became a reined, ideological category” (Horkheimer 1982b, p. 194). Also,

early Frankfurt School works are devoted to an open rational Enlightenment from an interdisciplinary scope. Within this, intellectual realm studies on working-class attitudes in Weimar Republic and the *Studies on authority and family* (*Studien über Autorität und Familie*, 1936) are particularly relevant.

The experience of exile and Nazism had a huge impact upon different members of the Frankfurt circle, albeit not only biographically speaking. In the field of theory, the Frankfurt School experienced a significant turn toward radical reports of the destructive power of social rationalization and its outcome. Historical facts such as the political drift of the Soviet Union, the explosion of European Fascism, the cultural dominance of the USA or the increasing working-class tendency toward integration and a certain welfare state, forced Horkheimer and the rest of the Frankfurt circle into rethinking the certainty of revolutionary processes in advanced societies. Besides, they had to rethink whether the interpretation of historical facts was to be undertaken through categories such as *class consciousness* or *class struggle* or not. Not only the increasing expansion of marketing, advertising, and consumer society but also the totalitarian path taken by the Soviet Union led the school to determine that Nazism was not unique or a barbaric state of exception. It was not an exception in history. In this new stage, Frankfurt School writers begin to talk about Nazism as the main symptom of something bigger: the clearest of modern societies’ tendencies, that is to say, inclination toward control of both men and things. At this point, Frankfurt School writers – Adorno, Horkheimer, and Marcuse in particular – will tend to overcome Marxist materialist procedures in order to track in human history those social and psychological elements which explain how the Enlightenment has become a social order of reification of both human critical resources and aspirations. These writers feel that concepts such as progress and rationality must be redefined. Their attitude toward philosophy, then, links them with the Marquis of Sade, Hobbes, Nietzsche, or Freud. Consequences of this move were clear: after

their common materialist dialectical framework is gone, the Frankfurt group disbands philosophically, and critical theory itself relates, from this moment on, only to the works by Horkheimer and Adorno.

Year 1942 is when this change becomes ultimately clear. Horkheimer writes and publishes *The Authoritarian State* (*Autoritärer Staat*, 1942). Highly influenced by the work of Walter Benjamin, Horkheimer traces the different forms of domination in advanced societies (including National Socialism, socialism, and capitalism). Horkheimer stresses non-economical forms of fastening and submission, and states that social change, less plausibly steady as the century goes, must become more of a break-up with historical logic than a powering of it. Thus, social reality is to be understood under the philosophical category of *totally administered world*. This designates a certain political evolution turning into the victory of the technical dimension of rationality, absolute codification of life, and the closure of social and political alternatives. Collective conscience is generated and put under control by mass instruments, and the subject is reduced to the point zero of being mere part of the production process. At this point in time, Frankfurt School representatives are devoted to cultural criticism, cultural theory, and social analysis of modern capitalist societies.

This is where *Dialectic of Enlightenment* (*Dialektik der Aufklärung*, 1947) points at. Written by Adorno and Horkheimer during the 1940s and published in 1947, this work still ranks as the landmark for critical theory and, moreover, among the most influential books of the century. Here is presented a relentless critique of historical progress by showing the relationship between myth and Enlightenment, reason, and domination, stating that “in the enlightened world, mythology has permeated the sphere of the profane” (Adorno and Horkheimer 2002, p. 21). Therefore, the myth is already Enlightenment – myth is to be understood here between its ancient Greek meaning of true story, which unveils the origin of something, and its present meaning as a false popular belief – and Enlightenment turns once more into mythology.

An insight in mythical, irrational, and violent aspects of modern reason reveals the particular dialectic of Enlightenment, according to which rational power, increasing freedom, and autonomy are slowly substituted by a model of rationality that does not only administrate the order of things without questioning it but also gives up when it comes to making this order appear reasonable.

Nazism became a paradigm for this process, for it showed how rationality and human horror can team up in perfect harmony. The model these societies adopt is that of instrumental reason – one-dimensional reason, says Marcuse – being its main features (1) an inner ambiguity and (2) an empty case: (1) instrumental reason can fully cooperate with human advance by helping its means being more efficient, but at the same time, it is not capable of proposing any end (to these means) at all. (2) *Instrumental reason* is just *particular reason*. Universal aims are out of its range. Due to certain dark points in Horkheimer and Adorno’s book, it has been said that what they propose is the return of irrational-sentimental-human motifs in western culture. This point is not clear, though. What Adorno and Horkheimer seem to defend is the fulfillment of the critical agenda of Enlightenment: they look for a culmination of *practical* reason, not for a collapse of reason. The expectations of enlightened practical reason can only be assumed after the recognition of a failure in modern advanced societies: technical rational procedures, even the most successful, do not entail the suppression of barbarism. The argument for the conversion of Enlightenment into myth eventually alludes to the process of socially executed domination through consciousness-oriented patterns and authoritarian role models only to be overpowered by radical social and philosophical criticism.

This diagnosis needed two more works to be developed, both by Horkheimer: *Eclipse of Reason* (1947) and *Critique of Instrumental Reason* (*Zur Kritik der instrumentellen Vernunft*, 1967), being the second an extended version of the first one. In both of them, Horkheimer depicts two dominant modes of reason in the western

world: (1) objective reason, whose activity leads to a still hierarchical order, and (2) subjective or instrumental reason. This leads to a sophisticated process of strategic choice of means to a previously determined end. Within the critical philosophy of the Frankfurt School, subjective reason is regarded as the most representative corruption of practical reason. Due to its inability to suppress its mythical content, Enlightenment has allowed reason to construct rationally inhuman orders – then again, Horkheimer has Nazism in mind when writing this. In terms of ends, Enlightenment has been living in denial; it has pushed everything but instrumental management into the background, but without stating to which ends were those means acceptable. The victory of the model of one-dimensional reason blocks critical thinking by eluding measuring the value of existence today.

Around this argument, Adorno and Horkheimer build an ideological and cultural critique of society that soon became one of the Frankfurt School main hallmarks. The central element of this argument is the critique of power and its interest in homogenization and integration, arranged by what Adorno has named the *cultural industry*. The analysis of ideological reproduction in advanced capitalist societies stresses how a distorted perception of reality and the high pressure on private ways of living relate to the disappearance of genuine aesthetic experiences and any conflict whatsoever between culture and society. Thought and culture are mass controlled, and they do not discern anything different beyond the current cultural horizon. The entertainment net, as well as knowledge itself, reaffirms a still approach to social reality.

Loyal to the critical-negative configuration of their theory, Adorno and Horkheimer do not present a positive model of collective practical reason, but it is also relevant to note that general assumptions of critical theory point at a total recovery of creative-critical reason. Therefore, reason perverts itself as long as it does not think the best out of itself. For Adorno and

Horkheimer, it is not about absolute intellectual security but about a model of critical thinking enabled to generate a whole set of practical human ends.

Critical theory then charges the hard core of its critical thinking with *negation*, alongside the dialectical tradition of western philosophy. Philosophy is to be understood as the struggle for not subduing. But negation, as Horkheimer himself has argued, offers two different sides: on one side, it is the negation of ideology. On the other, it is negation of the insolence of reality. This negative position finds its highest expression in Adorno's late work *Negative dialectic* (*Negative Dialektik*, 1966). In Adorno's view, dialectical thinking does not have to lead to a new ultimate system of thinking but to the recognition of the perennial character of contradiction, difference, and contingency. Against those who comprehensively close the system – namely, the thinkers of *identity* – Adorno's philosophy accounts for complexity and antagonism. Totality and harmony are just not compatible. Even though Adorno is insistence on this position, it has been argued that critical theory has put too much weight on its interpretation of this *closed totality*, which seems to define the whole social, economical, cultural, and juridical system. All these institutions are regarded as totalitarian means to a totalitarian end, and therefore, Adorno and Horkheimer would have misunderstood inner differences between contemporary social systems (liberal democracies and the Soviet Union, particularly). What cannot be disdained, though, is Adorno's definitive closure of the possibility of making reality more rational by developing specific policies. Social transformation, he argued, needs to be thought in terms of a *redemption* which at the same time cannot be mentioned in any way but the negative way. This point of view of redemption or *negative theology* has been interpreted by many scholars and religious thinkers in terms of resignation before the definitive judge on systematic thinking and modern empathic reason: Adorno has famously put this as the fact that philosophy's survival

has to do with the fact that the moment of its realization was missed.

Providing ground for many of these arguments stands the work of Walter Benjamin, whose intellectual presence in Adorno's work is invaluable. Although his philosophical exchange with Horkheimer never proved fruitful, Benjamin's attention to cultural detail, religion, time, history, and historicity did have an impact upon Adorno's negative dialectics. Also, Benjamin developed a highly influential theory of experience, according to which modernity and mass media entail an impoverishment of experience (in social and cultural terms) but not necessarily the annihilation of critical thinking. Adorno and Benjamin shared a vivid interest in a theory of interpretation of modern capitalist culture as part of a whole attempt to understand modernity. This attempt is not only about cultural forms. It is about the work of art itself in modern times. Summarizing, Benjamin brings modernity and spatializing together. That is to say, there is no science if we do not trace the extremes of our object: its history. No insight into the realm of art can possibly avoid the completion of the history of its objects. This idea is also relevant in terms of Adorno's critique of music. In his *Philosophy of new music* (*Philosophie der neuen Musik*, 1949), he argues that we can only get to know our objects (musical works of art, that is to say, works in which duration plays a major role) when going through their extremes. Only these extremes guarantee the recognition of their truth content. This approach gets back to certain hermeneutics of cultural forms of capitalism or, in other words, to a physiognomy of history in terms of hermeneutics of the (hidden) natural history of cultural objects. Adorno, not far from Benjamin, argues that the origin of the artwork is to be grasped in its pre- and post-history. The extremes of the artwork are the sign of its main features: it reflects the rest of the world – the whole capitalist system. Its essence is not pure history but natural history.

The natural life of the artwork, its inner history, develops clearly as a kind of relationship according to which its nature is historical and its

history natural. Pre- and post-history means to extract the historical dimension registered in the idea of the artwork. In terms of Adorno's book on new music, it is not about different styles and periods but about the procedural constellation in which the work emerges. This is extremely coherent with Benjamin's claim that art criticism is actually mortification of the work of art. To mortify a work of art means to approach a hermeneutical mediation toward a materialistic theory of interpretation. To put it another way, to mortify is to obtain the *dialectical image* of the work. Both Benjamin and Adorno twist nature and history in order to challenge the usual approach to natural history, that is to say, the very idea that natural history means taxonomy, nature as something that is always previously given to us. Right now, Benjamin and Adorno are placing natural history where the only dialectical bound between nature and history is no more opposition but transience (passing-through). Among Benjamin's major works are to be found *The origin of German tragic drama* (*Ursprung des deutschen Trauerspiels*, 1925), *One-way Street* (*Einbahnstraße*, 1928), "The work of art in the age of its mechanical reproduction" (*Das Kunstwerk im Zeitalter seiner technischen Reproduzierbarkeit*, 1935), *The Arcades Project* (unfinished, *Das Passagen-Werk*, 1927–1940), and the "Theses on the Concept of History" (*Geschichtsphilosophische Thesen*, 1940).

Another key figure within the Frankfurt School is Herbert Marcuse, even though his work cannot be assimilated to the work of Adorno and Horkheimer. His philosophical background, far from being strictly dialectical, was oriented toward Husserl's phenomenology and Heidegger's ontology. Marcuse attended the well-known Freiburg lectures by the latter. After this formation period, from which comes his relevant work *Hegel's Ontology and the Theory of Historicity* (*Hegels Ontologie und die Grundlegung einer Theorie der Geschichtlichkeit*, 1932), Marcuse found in Marxist philosophy a possibility for more social content for his theory. After Heidegger's *Being and Time*, Marcuse gets increasingly closer to some Marxist

principles. In his remarkable *Reason and Revolution* (1941), Marcuse inserts Hegel in the realm of Marxist thinking by underlining the notion of *praxis* in his work. Marcuse's standpoint is opposed to that of Adorno and Horkheimer, regarded as overrated theoreticism, and pays special attention to the action of social forces and shows steady faith in the final reconciliation of mankind and reality. The writings of young Karl Marx and Freud are also relevant sources from which Marcuse develops his liberation project. This would consist of putting *the great denial*, that is to say, the withdrawal of alienating forces by promoting gratification instincts, the fair use of technology and the political action of the worst off. His works have also been influential for its utopian charge. These are particularly interesting: *Eros and civilization* (1955), *Soviet Marxism* (1958), *An Essay on Liberation* (1969), and above all, *One-dimensional man* (1964).

Also, a very well-known critical intellectual next to the Frankfurt School was the psychoanalyst Erich Fromm. In the beginning, Fromm added to the common Marxist background of the group his strong interest in anthropological and spiritual issues. It is in this sense that Fromm finds human alienation only to be disrupted by a suppression of violence and depersonalization. Fromm revised this position in the 1940s with strong consequences: now far from Frankfurt, Freud's presence diminished and the stress on humanitarian aspects, ethical life, and oriental religions was increased. But Fromm always kept the concept of human nature and the road toward emancipation in mind. His main works are *Escape from freedom* (1941), *Psychoanalysis and Religion* (1950), *The Art of Loving* (1956), *Psychoanalysis and Zen-Buddhism* (1960), *The Anatomy of Human Destructiveness* (1973), and *To Have or to Be?* (1976).

Summarizing, the Frankfurt School presented a model of critical thinking and radical enlightened critique of reason and Enlightenment itself. Besides, in the surroundings of the Institute, many political and economical researchers could publish and present their contributions.

Some of them were ostracized and others never got along with the Institute of Social Research's patterns. *Behemoth*, a study of National Socialism written by Franz Neumann (1900–1954) in 1942, and *Punishment and Social Structure* (1939) by Otto Kirchheimer (1905–1965) and Georg Rusche have also been influential in historiography and social sciences. The work of these authors highlights the weak points in critical theory: the lack of accuracy and critical development of political, institutional, and economical categories; also, it has been said that, up to a point, the Frankfurt School never got rid of certain cultural elitism and theoreticism. This arguably misled Adorno and Horkheimer, and got them progressively further from social problems and politics. Different generations of the Frankfurt School have later tried to solve these issues, being Jürgen Habermas its main representative. Habermas' research manages to transcend the philosophical edges that limited Adorno and the first generation's work without letting its critical hardcore slip. He has also tried to inscribe critical theory in the realm of language, communicative action, and the normative foundations of the state. His work has been widely discussed both in the USA and overseas, specially his works *Theory and Praxis* (*Theorie und praxis*, 1963), *Knowledge and Human Interest* (*Erkenntnis und Interesse*, 1968), *Theory of Communicative Action* (*Theorie des Kommunikativen Handelns*, 1981), and *Faktizität und Geltung* (1992). One of Habermas's students, Axel Honneth, has also developed a strong interest in power, recognition, interpersonal relations, and justice. Honneth's philosophical exchange with Nancy Fraser and his work on recognition have proved very fruitful. Honneth's research program focuses on the paradoxes of capitalism and its structural social transformations, and remains the last stage in the Frankfurt School's history so far.

Religious debates involving critical theory have arisen in the last 20 years, particularly after the tearing down of the Berlin wall and the dissolution of the Soviet Union. The debates about Fukuyama's "end of history"

argument have had religious implications. The secularization processes, the pessimistic views on mankind's ability to cope with technique, and the idea of history as an evolutionary process drew out in the early 1990s strong debates about religion's role in a democratic-liberal closed world, as Fukuyama had projected. In the last decade, some political philosophers have argued that radical Islamism (Fukuyama himself) constitutes the kind of menace that fascism and communism were from the early 1920s onward. Critical theorists like Perry Anderson (or even Jacques Derrida, both in different senses of the terms *critical* and *theory*) have been extremely reluctant to Fukuyama's claim, arguing that the end of history can only be about either getting rid of Marx (Derrida) or, as Anderson has criticized, about imposing an existing order *sub specie aeternitatis* (which would consist of a world permanently based on strong liberal democracies in a peaceful environment). Many scholars and intellectuals are currently discussing related issues, including (1) the problematic relationship between religion, rights, and immigration (France, the USA, the UK, etc.); (2) the links between religious practices and contemporary art; and (3) the philosophical implications of political theology (Carl Schmitt, Johann Baptist Metz) in the range of critical theory, society, and ecology. Also, there is (4) an ongoing discussion about the relationship between Freud's and Lacan's psychoanalytical approach, the Christian neighbor with the otherness that entails, and the critical theory of Benjamin and Adorno. Horkheimer himself argued, in the mid-1960s, that thinking about Kant was thinking about reason defending itself against its new enemies by means of reason. It is in the sense of this huge task that one might argue that the Frankfurt School and critical theory in a broader sense, which includes Robert Kurz, Heinz Steinert, Perry Anderson, Fredric Jameson, Terry Eagleton, Judith Butler, Seyla Benhabib, Slavoj Žižek, Ernesto Laclau, Bob Jessop, Antonio Negri, David Harvey, or Moishe Postone, among others, are about both a new

philosophical agenda but also about new perspectives on different scientific traditions.

Critical Realism in Theology and Science

[Theological critical realism](#)

Description

The term *critical realism* (CR) figures widely in philosophy, theology, and the dialogue between theology and science. It turns up in different contexts, sometimes independently of earlier uses. Hence, it is not surprising that its uses vary substantially. Nevertheless, it is possible to point out some core ideas which apply to most, if not all, kinds of CR described below.

Generally speaking, CR is the view that it is possible to acquire knowledge of an external, mind-independent reality. This view contrasts with phenomenism, which holds that knowledge is, or should be, restricted to the description of phenomena (or perceptions) and their relations. CR presupposes metaphysical or ontological realism, which holds that there exists a mind-independent reality. Thus, it denies metaphysical idealism, which holds that reality has, or essentially has, a mental nature. For these reasons, CR is called *realism*.

The qualification *critical* distinguishes CR from so-called naive realism, which claims that reality is as it is perceived. CR acknowledges that we have no direct access to reality. Knowledge of reality is always mediated by the human mind. Therefore, it is constrained by the limitations of human perception and cognition. As a consequence, alleged knowledge of reality is at best partial or approximate, and it will always be possible to subject it to criticism and improvement. The critical nature of CR is often

elucidated with reference to Immanuel Kant's concept of critique as reason's recognition of its own possibilities and limits, which entails criticism of knowledge claims that disregard those limits.

In the various kinds of CR, reality is primarily specified as the natural or physical world. However, reality may also be held to include history, the social world, or God. Further, the mental mediation of knowledge may be regarded as a feature of individual cognition, but also as connected with the social nature of knowledge and its historical transmission. Finally, in its most elementary sense, CR is just the view that it is possible to acquire knowledge of external reality. However, it often involves methodological considerations as part of a justification of the realist bearing of scientific or other beliefs. The concept may even be extended to encompass a full-fledged philosophy including ontological and even ethical tenets.

Critical Realism in Philosophy

The term CR appeared for the first time in German philosophy. Since the end of the nineteenth century, it here designates those positions that take account of Kant's critical epistemology but deny that the mental nature of perception and cognition totally prevents us from acquiring valid knowledge of the external world as it is in itself. More specifically, the term refers to the view of C. Stumpf and others that reflection on sense-data can convey knowledge of certain features and relations of the external world.

In the 1920s, CR became the name of a movement in American philosophy, which was represented, among others, by Roy Wood Sellars (1880–1973) and A.O. Lovejoy (1873–1962). This movement sought to integrate insights of idealism and new realism. New realism was a reaction to nineteenth century idealism, against which it claimed that there exists an external, physical world and that perception and cognition convey direct access to it. American CR agreed with new realism that it is possible to

acquire knowledge of the external world, but disagreed with the thesis of direct access, which it regarded as a form of naive realism. It pointed out that our access to the external world is mediated by mental representations of its objects, which cannot be identified with the objects themselves. Only by recognizing this, error, illusion, and perceptual variation can be accommodated.

Through the work of Wilfrid Sellars (1912–1989), Roy Wood Sellars' son, American CR influenced scientific realism (SR), which arose in the 1950s in opposition to the positivist view of science. Although SR only seldom is designated as CR, it is discussed here because (1) it shares the general characteristics of CR so that it may be regarded as an elaboration of CR in respect of the philosophy of science and (2) it has exerted substantial influence on CR in the dialogue between theology and science.

SR opposes the positivist ideal of science as consisting merely of propositions about observables. For positivists, scientific theories that transcend the phenomenal world (e.g., by positing unobservable entities such as electrons) do not refer to real structures and entities of the external world. Such theories may be useful instruments for the ordering and prediction of the phenomena, but they have no realist bearing. In opposition to this view, SR states that successful scientific theories tell us something about real structures and entities of the world. Often SR includes the idea that progress in science gives us an increasingly reliable picture of reality. According to Stathis Psillos (b. 1965), one of its principal advocates, SR comprises three theses: (1) The world has a definite, mind-independent structure (metaphysical realism). (2) Scientific theories are descriptions capable of being true or false relative to the reality they intend to describe (semantic realism). (3) Mature and predictively successful scientific theories are approximately true and the entities posited by them inhabit the world (epistemic realism) (Psillos (1999)). The idea of truth approximation revives Karl Popper's notion of verisimilitude. Ilkka Niiniluoto (b. 1946) has given a formalized version of this notion, which

plays a central part in his account of SR (which he calls "critical scientific realism").

The main argument in favor of SR is that the best explanation of the empirical success of science is that its theories are approximately true. This argument has been accused of being viciously circular in that it argues for the truth of scientific theories by means of the very kind of reasoning (i.e., abductive inference) upon which those theories are based. Abductive inference is a mode of reasoning to find plausible scientific hypotheses. According to C.S. Peirce (who coined the term) it has the following form: The surprising fact, C, is observed; But if A were true, C would be a matter of course; Hence, there is reason to suspect that A is true. Moreover, the objection has been raised that empirical success does not warrant a theory's truth. The reason is that the phenomena may permit different theories because the latter are underdetermined by the former. In this connection, critics point to the fact that many once successful theories have been abandoned now. The advocates of SR reply that the circularity of the argument is not a vicious one, because its conclusion does not rest upon the presupposition that scientific theories are true. Further, they argue that SR is not a global view of science but has to be established for each theory in particular. Empirical adequacy is not a sufficient criterion here. It has to be supplemented with criteria such as consistency, coherence with other accepted theories, and long-term fertility. Finally, they emphasize that SR does not claim that successful scientific theories are true, but only that they are approximately true.

In 1975, Roy Bhaskar (b. 1944) presented a general philosophy of science named "transcendental realism," which was followed in 1979 by a philosophy of the human sciences named "critical naturalism." Gradually his followers designated these philosophies together as CR. Bhaskar has accepted this designation, arguing that "critical" rightly suggests affinities with Kant's epistemology while the ontological denotation of "realism" indicates the differences from it.

With Thomas Kuhn and others, Bhaskar emphasizes the social nature of science, but, in

opposition to “postmodern” relativism, he contends that science conveys knowledge of an independent reality. Starting from the phenomena, through modeling, experimentation, and other empirical control, science discovers causal laws. Such laws should not be considered as constant conjunctions of events (as does positivism) but as expressions of generative mechanisms that are part of the real world. Since these mechanisms may be explainable in terms of more fundamental mechanisms, the world is to be regarded as a stratified whole. Higher levels emerge from deeper ones but are not necessarily reducible to them. Consequently, each level demands its own specific method of scientific investigation.

In his “critical naturalism,” Bhaskar applies these ideas to the human, especially the social sciences. “Naturalism” indicates that there is a fundamental similarity between the social and natural sciences in that both are concerned with the discovery of intelligible connections in the real world. At the same time, Bhaskar stresses the specificity of the human sciences resulting from emergent properties of the social world. These properties relate to the fact that society, in contradistinction to nature, is the condition as well as the outcome of human agency, which both reproduces and transforms it. Hence, social systems are intrinsically open. As a consequence, unlike the natural sciences, the social sciences rely exclusively on explanatory (and not also predictive) criteria for theory assessment. Further, they enable scientific criticism of social structures that produce false beliefs, which involves the incitation to remove or transform those structures. Thus, Bhaskar’s CR entails the claim that it dissolves the traditional fact/value and theory/practice dichotomies, and passes into ethics. Here, “critical” no longer merely refers to epistemological critique but also to substantial criticism of beliefs and social structures.

In what he called “dialectical CR,” Bhaskar developed these ideas to a general theory of identification and elimination of “absences” (deficiencies) for the sake of socialist emancipation. Obviously, this theory draws from Marxist wells. At the same time, “critical” now also

signals affinity with the critical theory of the *Frankfurter Schule* (Archer et al. (1998)).

Critical Realism in Theology

Bruce L. McCormack has characterized Karl Barth’s (1886–1968) theology as a “critically realistic dialectical theology.” He justifies this characterization (which does not stem from Barth himself) with reference to the fact that Barth grounds theology in the reality of God as He reveals Himself in Jesus Christ. At the same time, Barth’s theology is critical in the sense that it presupposes the validity of Kant’s epistemology and critique of metaphysics. Due to the limits of reason, according to Barth, knowledge of God is possible only by God redirecting our cognitive apparatus through which He makes us participants in His knowledge of Himself.

In the Catholic tradition, Bernard Lonergan (1904–1984) developed a theory of knowledge, which he named CR. On the basis of an analysis of actual knowing, he concludes that cognition involves experience, understanding, and judgment that tests understanding. Combined properly, these elements convey objective knowledge of the real world. At the same time, they constitute the transcendental foundation of the methods of all sciences, natural as well as human. In the designation “CR,” “critical” indicates the similarities with Kant’s critique of reason, while “realism” refers to the realist bearing of proper cognition. Having extended this CR with the notion of decision, Lonergan used it to define the method of theology. In conformity with the demands of cognition and morality, the theologian has to make responsible decisions as to which traditional doctrines should be taken up for systematic understanding and translation into the cultural milieu. In this connection, Lonergan stresses the importance of intellectual, moral, and religious conversion (Dunne (2005)).

Several biblical scholars have incorporated critical realist ideas into New Testament

hermeneutics. Inspired by Lonergan, Ben F. Meyer (b. 1927) states that interpretation should concern itself with the intended sense of the text and the realist truth claims involved in it. N.T. Wright (b. 1948) bases a critical realist hermeneutic on the thesis that knowledge of the real world always is framed by a worldview, of which stories are an essential part. Cognition proceeds through testing hypothetical stories on their “fit” with stories already in place, which may give rise to modify them or formulate new stories. With regard to the interpretation of the New Testament, a critical realist hermeneutic recognizes the subjectivity of both the author and the reader, but claims at the same time that this subjectivity does not necessarily preclude an understanding that gives access to the external realities dealt with by the text. Moreover, it takes seriously the theological view of reality as a whole, including God (Wright (1992)).

Critical Realism in Theology and Science

The term CR was introduced into the dialogue between theology and science by Ian G. Barbour (b. 1923) in 1966. Inspired by SR, Barbour uses the term to denote a realism that acknowledges the creativity of the human mind but also takes seriously the cognitive claims of both science and religion. He connects CR especially with the role of models in science and religion – e.g., the atomic model and the image of God as a father. Such models are systematically developed metaphors which can tell us something about unobservable aspects of reality, though only in partial and inadequate ways. On the other hand, Barbour also stresses the differences between scientific and religious models due to the fact that the latter relate to existential questions of ultimate concern.

CR was elaborated for the science-theology relationship by Arthur Peacocke (1924–2006). Peacocke asserts that, similar to science, Christian faith depends ultimately on experience, viz., religious experience of God as the all-encompassing reality. Moreover, both the

scientific and the Christian communities serve to secure continuity of reference, the latter by transmitting the initial experiences of God and linking them to new ones. Theology has the task to interpret religious experience in connection with reflection on the world, using metaphors and models as science does as well. Theology and science are, or should be, interacting approaches to reality. At the same time, it is the hallmark of theology that, by virtue of its concern with reality as a whole, it constitutes the highest level of integration (Peacocke (1984)).

John Polkinghorne (b. 1930) developed CR somewhat differently. According to him, CR considers intelligibility a guide to ontology. Therefore, the progress of scientific understanding gives us increasing verisimilitudinous knowledge of the world. Science and theology are engaged in a common quest for understanding. There is, however, an important difference with regard to the role of models. While models in science merely have a provisional, heuristic function and often are replaced by mathematical theories, theology can only speak of God in a variety of models using symbolic language. Nevertheless, because it contributes to the intelligibility of the world, also theology can legitimately claim to convey verisimilitudinous knowledge. Polkinghorne even parallels the development of the Christological doctrine in the early Church with the development of quantum physics, though recognizing that the former merely led to a delimitation of the range of discussion, not to the formulation of a positive theory.

During the last quarter of the twentieth century, CR was the dominant epistemology in the dialogue between theology and science. However, from the 1990s onward, the transfer of CR from science to theology has met with growing skepticism. The main reason was the consideration that this transfer does not sufficiently take account of the differences between theology and science. The criticism of Ernan McMullin, a prominent representative of SR, was of seminal importance. McMullin points out that alleged evidence in theology (e.g., religious experience) not by far has the intersubjective strength of

empirical evidence in science and that there is no consensus about the criteria of theory assessment in theology, as there is in science. Moreover, theology cannot appeal to an explanatory success similar to that of science, the success of which is the main argument for SR. Therefore, the fact that the objects of both science and religion are beyond literal description is not a sufficient reason to transfer CR from science to theology (McMullin (1985)).

In 2002, Alister E. McGrath's (b. 1953) "scientific theology" introduced Bhaskar's CR into the field of theology and science. McGrath draws his main inspiration from Thomas F. Torrance (1913–2007), who, on the basis of Barth's Christocentric realism and in dialogue with the sciences, developed a theology of incarnation and creation. In the same vein, starting from God's revelation in Christ, McGrath's scientific theology explores God's relationship to the created world, taking account of scientific insights. This theology incorporates Bhaskar's ideas that scientific investigation is a response to an independent reality, that reality is stratified, and that the method of a specific discipline must be determined by the nature of its object. A Barthian view of theology is combined with Bhaskar's CR. One consequence is that God, as the one who causes all else to exist, is considered the most fundamental stratum of reality, and theology, being the study of God, is placed at the base, not at the apex, of the sciences (McGrath (2002)).

Critical Theory

Department of Social Sciences and Philosophy,
University of Jyväskylä, Jyväskylä, Finland

Related Terms

[Frankfurt school](#); [Marxism](#)

Description

Critical theory is a school of thought that stresses the examination and critique of society and culture, drawing from knowledge across the social sciences and philosophy. Critical theory aims at explaining and transforming the circumstances that enslave human beings, as Max Horkheimer defined the term in his now famous 1937 article *Traditional and Critical Theory*. Critical theory in most of its main form

has at least two main elements. Firstly, it is held that empirical study and philosophical analysis should be brought together to form a detailed and correct understanding of a phenomenon under study. Secondly, it is held that the normative basis for the critical research and critique should be founded on the needs, longings, and moral demands of the people living under the conditions of the system or structure that are criticized.

The above definition leads to two different ways to articulate critical theory: one a narrow sense and the other a broad sense. Critical theory, in the narrow sense, points to a several generations of long tradition of German philosophers and social theorists in the Western European Marxism known as the Frankfurt School. According to these theorists, a “critical” theory may be distinguished from what they call a “traditional” theory according to its specific purpose: a theory is critical to the extent that it seeks human emancipation.

Because such theories aim to explain and transform all the circumstances that enslave human beings, many “critical theories” in the broader sense have been developed. They have emerged in connection with the many social movements that identify different dimensions of the domination of human beings in modern societies. In both the broad and narrow senses, a critical theory provides the descriptive and normative bases for social inquiry aimed at decreasing domination and increasing freedom in all their forms. In this sense, any philosophical approach with similar practical aims could be called a “critical theory,” including feminism, critical race theory, and some forms of postcolonial criticism.

Critical theory, in the narrow sense, has had many different aspects and quite distinct historical phases that cross several generations. The Institute for Social Research (founded in 1928) saw the arrival of the Frankfurt School theorists (Erich Fromm, Theodor W. Adorno, Friedrich Pollock, Walter Benjamin, Herbert Marcuse, Leo Löwenthal, Jürgen Habermas, Axel Honneth) after Horkheimer gained the directorship of the Institute in 1930. Its distinctiveness as

a philosophical approach that extends to ethics, political philosophy, aesthetics, psychology, philosophy of language, and the philosophy of history is most apparent when considered in light of the history of the philosophy of the social sciences.

Critical theorists have long sought to distinguish their aims, methods, theories, and forms of explanation from standard understandings in both the natural and the social sciences. Instead, they have claimed, in line with Horkheimer’s 1930 inaugural lecture, that social inquiry ought to combine rather than separate the poles of philosophy and the social sciences: explanation and understanding, structure and agency, and regularity and normativity. Such an approach, critical theorists argue, permits their enterprise to be practical in a distinctively moral (rather than instrumental) sense. They do not merely seek to provide the means to achieve some independent goal, but rather seek human emancipation in the circumstances of domination and oppression. This normative task cannot be accomplished apart from the interplay between philosophy and social science through interdisciplinary empirical social research.

A critical theory is considered adequate only if it meets three criteria: it must be explanatory, practical, and normative. These criteria should be met all at the same time. That is, a critical theory must explain what is wrong with current social reality, identify the actors to change it, and provide both clear norms for criticism and achievable practical goals for social transformation. Any truly critical theory of society has as its object human beings as producers of their own historical forms of life. In light of the practical goal of identifying and overcoming all the circumstances that limit human freedom, the explanatory goal could be furthered only through interdisciplinary research that includes psychological, cultural, and social dimensions, as well as institutional forms of domination. Given the emphasis among the first generation of critical theory on human beings as the self-creating producers of their own history, a unique practical aim of social inquiry suggests

itself to transform contemporary capitalism into a consensual form of social life. A capitalist society could be transformed only by becoming more democratic in a rational society where all conditions of social life are controlled by human beings. The normative orientation of critical theory is, therefore, directed toward the transformation of capitalism into a “real democracy” in which such control could be exercised.

The focus on democracy as the location for cooperative, practical, and transformative activity continues today in the work of the second generation’s main philosopher Jürgen Habermas, as does the attempt to determine the nature and limits of “real democracy” in complex, pluralistic, and globalizing societies. Axel Honneth, who is the main theorist of the so-called third generation, has further developed the first and the second generations’ theories into what he calls the theory of recognition. As might be expected from such an ambitious philosophical project and form of inquiry, critical theory is rife with tensions within the same generation and between the different generations of the tradition.

Critical Thinking

Sharon L. Coggan

Department of Philosophy, University of Colorado Denver, Denver, CO, USA

A scholarly norm applied across the board in all academic fields represented in the modern university including Religious Studies. The critical thinker applies reason and logic to everything under examination; weighs evidence; considers counter positions; draws tentative conclusions based on carefully examined available evidence; considers the source and validity of all information; is careful to acknowledge sources of information with a cognizance of their limitations; is attentive to the soundness and logical progression of argumentation ; and approaches any and all subjects objectively, in an unbiased, fair, reasonable manner.

Comparisons; Cultural diversity; Cultural variations; Global psychology; Multiculturalism; Relativism cultural; Universality

Description

Psychological science consists of a number of perspectives and methodological approaches to research and modes of inquiry. These include the developmental, experimental, quantitative, qualitative, and other modes. One of the other approaches that has enjoyed growing popularity during the past several decades is cross-cultural psychology.

Sometimes called culture-comparative psychology or multicultural psychology, the main aim of this approach is to expand psychology's horizons by "extending the range of variation" of psychological variables so that psychology will become increasingly inclusive and enriched by examining virtually any theory or finding in the discipline to determine their generalizability (Berry et al. 2002; Matsumoto 2001; Matsumoto and Juang 2008). For instance, do the laws of learning and memory and cognition established largely in Western cultures hold true everyone around the globe? If not, why? And what might be done to rectify the situation? The same could be asked of perceptual processes, intelligence and abilities, personality development, psychopathology, and many other approaches to studying the nature of individuals who often grow up in strikingly different cultural contexts. Social psychological perspectives, mixed with cultural inquiries, are especially prevalent in contemporary cross-cultural psychology (Smith et al. 2008). Largely, then, cross-cultural psychology

can be considered as a psychology "writ large" – that is, it encompasses all human thought and behavior, doing so by using the traditional tenets of psychological science.

Relatively recent developments include the founding in 1970 of the *Journal of Cross-Cultural Psychology*, the formation of the International Association for Cross-Cultural Psychology in 1972, the publication of hundreds of books in the area, and additions to psychological curricula throughout the world that features the psychological study of culture.

The *Journal of Cross-Cultural Psychology* (JCCP) is exclusively devoted to the publication of research in which culture plays a critical role. JCCP recently published a special issue entitled "Religion and Culture: Perspectives from Cultural and Cross-Cultural Psychology". This is an important development because religion, at least to some extent, is part of culture. It interacts with other components of culture and thus plays a role in many aspects of the psychological functioning of individuals and groups across the globe. It is for this reason, either explicitly or implicitly, that religion is of particular interest for cultural and cross-cultural psychology. Differences and universals across religions may parallel, if not contribute to and explain, cross-cultural differences and universals in other domains of functioning. The way groups (cultural-ethnic and/or cultural-religious ones) differ or resemble each other on their religious beliefs, emotions, and practices may reflect, or have an impact on, the way these groups' members deal with most if not all the psychological aspects of their life. These include how "self" is defined with respect to cognition, emotion, motivation (Markus and Kitayama 1991), values, morality, interpersonal and intergroup relations, life span development, health, and social behaviors related to work, marriage, leisure, economics, and politics (Smith et al. 2008).

Self-Identification

Science

Cross-cultural psychology identifies itself as a science in exactly the same way that its "parent"

discipline identifies itself as a science. It does so by using essentially the same tools of methodological inquiry, while at the same time having to deal with special methodological problems such as sampling and issues of equivalence. There is no reason for it not to self-identify as a totally independent science.

Characteristics

It is distinctive among the others because it explicitly focuses on culture as an important factor in all topics within psychological science.

Relevance to Science and Religion

Cross-cultural psychology, as a subdiscipline, is interested in the area called “science and religion” only to the extent that religion, as an important phenomenon for millions of people, helps to shape many and, perhaps for a great number, all facets of their lives. However, many psychologists (including cross-cultural psychologists) have little or no interest in studying religion by employing the canons and methods of science. An exception, however, is the study of values, beliefs, and attitudes, which represents a sizeable portion of cross-cultural psychological research. One could argue that religions largely consist of a set of beliefs, an assortment of values, and a number of attitudes. As noted earlier, the *Journal of Cross-Cultural Psychology*, which is the flagship journal of this specialized approach, recently published, for the first time, a special issue on religion and culture.

Sources of Authority

The sources of authority include the massive amount of psychological knowledge that has accumulated for many, many years – even going back to the early Greeks and the scholars and philosophers they influenced. The main contemporary authorities are the leading theorists and

methodologists in the area. The references below provide a sampling of authoritative readings.

Ethical Principles

The ethical principles used are exactly those used in “mainstream” psychology. However, special attention is given to the sensitivities of people from other cultures, under the belief that it would be unethical to exploit them for any reason other than to help understand the nature of their cultures. This rationale is identical to reasons psychologists study individuals and groups in their own milieu.

Key Values

The key values are the values that any scientist holds in studying the subject matter objectively and carefully. For cross-cultural psychologists, it is important to them not to exploit other cultures for their own professional reasons (e.g., to add to their list of publications). Culture-oriented psychologists simply wish to know how other cultures and their inhabitants function. The numerous methodological arrows in their quivers require careful consideration of what they are doing in the realm of ethics and decency.

Conceptualization

Nature/World

The discipline generally subscribes to the premise that nature, including human nature, and the nonhuman world as phenomena that can be understood by using the depth and rigors of the scientific method. Realizing that the challenges are many and endless, cross-cultural psychology endeavors to contribute to these challenges in any way that makes good, solid sense.

Human Being

Like most scientists who study human behavior, the Darwinian perspective, as well as various

related biological and medical sciences, is believed to be adequate to study most of the mental and physical processes of all people, regardless of culture. Studying religion scientifically may be beyond the realm of the “objective” and “nonspirit” world. Note also that it is not necessary for psychologists to address studying religion “scientifically,” but they can do so if warranted.

Life and Death

Cross-cultural psychologists may occasionally and selectively approach issues of life and death primarily because they are universal aspects of being human and because they can be profoundly affected by culture. That is, beliefs and attitudes about life and death are often part of socialization processes in growing up in different societies and cultures.

Reality

Since most psychologists are empiricists and imbued professionally with a sense of scientific objectivity, “reality” is that which can be measured and understood by careful research. Cross-cultural psychologists, like nearly all psychologists, respect and expect reports of “reality” to vary across cultures.

Knowledge

To psychologists and other scientists, knowledge gained through the use of the scientific method is cumulative. As such, the pool of knowledge expands greatly and continuously, and cross-cultural psychologists use it in their research.

Truth

All scientists believe that “truth” can be somewhat ephemeral, elusive, and tentative. Today’s truths can be tomorrow’s falsehoods and such is the nature of scientific inquiry. “Truth” observed and understood across cultures may be more ephemeral and evasive in a broad range of cultures because of methodological problems that must be solved wherever research involving other cultures takes place.

Perception

It is axiomatic and widely established that perception (visual, auditory, tactile, etc.) can be, and usually is, affected by both culture and ecology. Variations in perception are usually understood by a cross-cultural psychologist to mean that these processes are adaptive because of cultural conditions and the nature of the ecological forces to which individuals adapt and function. For instance, culture and ecology affects the perception of visual illusions, sensitivities in hearing, the perception of time, and so on.

Time

As indicated above, time (e.g., the passage of time, accuracy in estimating the passing of a minute, or the construction of a “calendar”) is usually treated objectively by cross-cultural psychologists. If time is meant to mean eons and geological eras, then the way time is used by cross-cultural psychologists can be different – as in Darwin’s theory. The study of time (e.g., accuracy in the perception of the passage of time) and space (e.g., the estimate of distances and size relationships) have been studied over the years by culture-oriented psychologists.

Consciousness

Consciousness has been studied by the ancient Greeks, empirical psychologists and psychoanalysts (such as Freud), and others for many years. The idea of “stream of consciousness” (a term coined by William James more than a century ago) is part of psychology’s scientific legacy. These cross-cultural psychologists can, and occasionally do, use the idea of consciousness in their research. William James’s well-known treatise on the varieties of religious experience is squarely in the realm of studying consciousness. Numerous cultural and medical anthropologists have studied altered states of consciousness that are often part of religious rituals. Some of this literature has influenced cross-cultural psychologists, especially in the mental health field (Ward 1989).

Rationality/Reason

Psychologists assume that as sentient beings, people throughout the world and across historical epochs have the capacity to think, to reason, and to solve problems – in general, to act “intelligently” in various cultural contexts. Psychologists interested in studying rationality and reasoning across cultures often construct tests and other devices to help them understand variations around the world.

Mystery

The word “mystery” is often used in psychology somewhat inquisitively, such as in the “mystery of the human brain,” the “mystery of the development of the self,” and the “mystery of human creativity.” In other words, how does the complex brain work, how do we develop a sense of self, and why are some people highly creative and others not? Mystery, in cross-cultural psychology, is not used as an epiphenomenon or as something associated with “not knowing” or beyond humankind.

Relevant Themes

All of the above covers a lot of ground. Generally, the juxtaposition of the words “science” and “religion” tends to raise eyebrows or hackles. This is because these two important words embrace, separately, different parts of an immense world of facts, beliefs, attitudes, methods of inquiry, and of course a bottomless pit of questions. These two words, when used together in intelligent and rational discourse, can be important to cross-cultural psychologists as they consider the nature and scope of their research.

Culture Industry

Eduardo Maura

Facultad de Filosofía, Universidad Complutense de Madrid (Spain), Madrid, Spain

A very characteristic term by Th. W. Adorno, culture industry gives title to the third chapter of his book *Dialectic of Enlightenment*, cowritten by M. Horkheimer. When analyzing popular culture, Adorno and Horkheimer diagnose that this consists of standardized cultural goods being distributed by mass media (radio, film, press, magazines, etc.). Particular aims of the culture industry, a term that Adorno always writes in singular, are to dominate and to control masses under a state of permanent consumption of enchanting goods and liquidation of critical thinking. This process of psychological, economical, metaphysical and social domination would end with a negation of true art and the impossibility for the right life, happiness, and social change.

Cyberethics

Herman T. Tavani

Department of Philosophy, Rivier University, Nashua, NH, USA

Related Terms

[Computer ethics](#); [Computer science](#); [Information ethics](#); [Internet ethics](#)

Description

Cyberethics is a branch of applied ethics that examines moral, legal, and social issues at the intersection of computer/information and communication technologies. This field is sometimes also referred to by phrases such as Internet ethics, computer ethics, and information ethics. The expression “Internet ethics” is somewhat narrow in scope and thus unable to capture the range of cyber-related ethical issues that arise independently of the Internet and networked computers per se. Because “computer ethics” connotes ethical issues affecting either computer professionals or computing machines, it also can easily fail to include a cluster of relevant issues that fall under the heading “cyberethics.” The expression “information ethics,” on the contrary, is too broad because it can refer to information-related ethical issues that are beyond the scope of cybertechnology. Additionally, “information ethics” as a field of applied ethics can be easily confused with a methodological framework that Floridi (1999) and others call Information Ethics or IE. (Floridi’s IE framework is intended as a “macroethical framework” for analyzing specific issues in cyberethics.) Thus, the term “cyberethics” best describes the set of ethical issues arising from the convergence of computer/information and communication technologies (Tavani 2004a, 2011).

An excellent historical account of key developments in this field of applied ethics can be found in Bynum (2008), beginning with his analysis of some insights in Norbert Weiner’s work

on cybernetics in the 1940s and 1950s that anticipated many of the issues that would eventually comprise the field of cyberethics as it is known today. Typical issues examined in cyberethics include, but are not limited to, personal privacy, intellectual property, cybersecurity, cybercrime, and the digital divide. In the final section of this entry, we briefly analyze a specific cyberethics issue involving privacy in the context of bioinformatics research.

Self-identification

Science

Cyberethics does not identify itself as a science, although, as an academic field, it does examine moral, legal, and social issues that arise in some scientific disciplines – viz., computer science and information science. Insofar as cyberethics employs empirical observation as an essential step in its overall framework for assessing relevant ethical issues, it incorporates a key element of the scientific method in its approach. However, other aspects of the methodological framework used in cyberethics are conceptual or analytical in nature, rather than empirical.

Religion

Similar to one aspect of religion, as an academic discipline, cyberethics is concerned with identifying, analyzing, and evaluating moral issues, including concerns involving social justice. The main difference is that cyberethics uses a philosophical method to approach moral issues rather than one based on religious authority, such as the Divine Command theory. Although cyberethics issues can be approached from the perspective of religious ethics, most of the current literature analyzes those issues from the point of view of one or more of three principal frameworks: philosophical ethics, professional ethics, or sociological/descriptive ethics (Tavani 2011). Some cyberethics authors, such as Spinello (2006), also use the framework of natural law theory, which has its roots in theological writings (most notably in the works of St. Thomas

Aquinas). An alternative to traditional ethical theories such as utilitarianism and deontology has been proposed by Gert (2004), who analyzes cyberethics issues from the perspective of his system of “common morality” (developed more fully in Gert 2005, 2007).

Characteristics

This question refers to what has been described as the “uniqueness debate” in cyberethics (Tavani 2002; Himma 2003). Some argue that cyberethics has unique ethical issues or properties that distinguish it from other areas of applied ethics (Maner 2004). Other ethicists, whom we can call “traditionalists” (following Johnson 1994), argue that there is nothing novel about ethical issues involving cybertechnology. It would seem that both groups offer a valuable insight into the nature of the issues examined in the field; however, both groups make some erroneous inferences. Traditionalists correctly point out that no genuinely new ethical issues have emerged because of cybertechnology; but these theorists also underestimate the fact that some moral issues affecting the use and development of cybertechnology pose a challenge for our traditional ethical frameworks.

Defenders of what we can call “the uniqueness view of cyberethics” correctly point out that cybertechnology has some unique technological features (e.g., in terms of its malleability and speed). However, they incorrectly go on to infer that the ethical issues associated with this technology must also be unique. Essentially, they commit the “CyberEthics Is Unique (CEIU) Fallacy,” which reasons as follows: Cybertechnology has some unique technological features; cybertechnology raises some ethical issues; therefore (at least some), ethical issues affecting cybertechnology must be unique (Tavani 2011). This reasoning is fallacious because it mistakenly assumes that features or properties that apply to a technology, X, must also apply to ethical issues associated with that technology.

Relevance to Science and Religion

Although cyberethics is not directly interested in many questions affecting science qua science or religion qua religion, it examines some issues and controversies that are of interest to researchers in both disciplines. Along with questions examined by some researchers in religion, for example, cyberethics asks questions such as “What does it mean to be human – i.e., in an era where nanotechnology and bioimplants can extend alter the conventional sense of ‘human’” (Moor 2005; Weckert 2006)? With regard to questions affecting scientific research, cyberethics asks whether the development of cybertechnology (as in the case of any new technology being developed) is “neutral,” i.e., value free, or biased in any way (Brey 2004; Friedman et al. 2008).

Sources of Authority

There are no “sources of authority” per se in cyberethics, but the field is guided by some empirical constraints similar to those in science, and it deals with some abstract issues that might be viewed as classic in moral analysis involving religion as an academic discipline. As far as a widely recognized source or figure in the field of cyberethics, the insights of James Moor (1985) in his classic article “What Is Computer Ethics?” have helped to guide research in computer ethics and cyberethics. In his seminal work, Moor introduced three important terms that have since structured and influenced the research of many philosophers in the field: “policy vacuum,” “conceptual muddle,” and “logical malleability.” Moor argues that because computer technology is logically malleable, it makes possible some novel ways of acting. This, in turn, creates some “vacuums” or voids in our policies and legal framework. However, before we can fill these voids by either creating new policies or revising existing ones, we sometimes first have to clarify muddles that arise. In this sense, Moor (1998, 2001) believes that cyberethics is justified as an independent field of applied ethics (independent of

the question of whether any cyberethics are unique ethical issues, as discussed above).

Ethical Principles

There are no specific ethical principles that guide cyberethics. Rather this field examines a range of ethical principles – from utilitarianism to deontology to natural law theory to contract/rights-based theories to virtue ethics, and so forth – to see how the various principles can be applied to ethical issues that arise at the intersection of computer/information and communication technologies. So, unlike some fields of applied ethics (such as biomedical ethics) that have a set of “received principles” guiding them, cyberethics is still at a point in its development where the ethical principles themselves are debated.

Key Values

Cyberethics has no key values as such. Rather, one of its principal tasks is to examine a range of values affecting professions, such as computing and information-technology professionals, as well as values affecting the discipline of computer science itself. So, an important task of cyberethics is to identify and analyze (implicit and explicit) values in relevant professions and disciplines affecting cybertechnology (see, e.g., Brey 2004).

Conceptualization

As a discipline, or a sub-field of applied ethics, cyberethics has no agreed-upon definitions or conceptualizations of terms such as Nature/World, Life/Death, Reality, Knowledge, Truth, Perception, Time, Consciousness, Rationality/Reason, and Mystery. In many ways, it employs standard philosophical accounts of reality, knowledge, and reason. The notion of reality has been challenged by research in virtual reality technology, and our standard conception of consciousness has been challenged by some of the

developments in artificial intelligence (AI). However, other notions such as nature, truth, time, perception, life and death, and mystery are not explicitly examined in cyberethics.

Relevant Themes

Issues/themes and concepts affecting “the good,” right/wrong, permissible/impermissible, obligatory/supererogatory, and justice are critical to cyberethics as a discipline. Also, concerns about gender issues affecting computers and cybertechnology have been examined extensively by Adam (2005).

A Specific Cyberethics Controversy Affecting Bioinformatics and Personal Privacy

As noted earlier, a wide range of moral, legal, and social issues are examined under the heading *cyberethics*. We also noted that these issues generally include concerns affecting personal privacy, intellectual property, cybersecurity, and cybercrime. Some recent controversies have also emerged in connection with convergent aspects of cybertechnology and non-cybertechnologies. For example, elements of cybertechnology have converged with biotechnology and nanotechnology to form new fields such as bioinformatics and nanocomputing, respectively. These fields, in turn, introduce concerns that pose additional challenges for some classic cyberethics issues such as privacy. We next briefly describe some ways that developments in bioinformatics threaten personal privacy, via a specific case example involving genetic databases.

What Is Bioinformatics?

Although there is no univocal definition of *bioinformatics*, the field incorporates principles and techniques from the broader field of *informatics*, which involves the “acquisition, storage, manipulation, analyses, transmission, sharing, and visualization of information on a computer” (Goodman 1998). So, *bioinformatics* can be

understood as the application of the informatics model to the management of biological information; its objective is to make that information more understandable and useful. Sometimes bioinformatics is used in ways that are synonymous with a sub-field called *computational genomics*; however, the latter field is more specialized since its primary use of informatics techniques and computational modeling is to analyze genetic/genomic data per se as opposed to broader biological data in general (Tavani 2006).

How Does Bioinformatics Research Threaten Privacy?

Bioinformatics research, particularly in the area of population genomics studies, has employed data-mining technology to analyze genetic information and “discover” patterns in DNA sequences affecting various populations and groups. Consider the case of deCODE Genetics (in Iceland) whose use of data mining illustrates the kinds of privacy concerns that arise in bioinformatics research. Many Icelandic citizens, who had been encouraged by their government to donate samples of their DNA to deCODE, assumed that information about their personal genetic data would be protected by either the company’s privacy policies or Icelandic privacy laws. However, Vedder (2004) points out that the kind of privacy protection that applies to personal information about individuals *as individuals* does not necessarily apply to that information once it is collected, aggregated, and cross referenced with other information. So the personal genetic information stored in deCODE’s genetic databases, once cross-referenced with information in that company’s databases containing nongenetic information (such as medical/health and genealogical information), was not entitled to the same kind of legal protection accorded to “individually identifiable personal information.”

Although data mining has helped researchers at deCODE and elsewhere to identify disease genes, this technology is controversial because it also generates *group profiles* (Custers 2006). Some groups can be constructed on the basis of profiles that are not obvious to the individuals who comprise them. For example, Custers notes

that a person who owns a red car may have no idea that he or she belongs to a group of individuals likely to have or to contract colon cancer (merely because of a statistical correlation that associates people who own red cars with colon cancer). Thus, a decision to deny an individual health insurance could be based simply on the “discovery” that the applicant owns a red car and would thus likely have a higher-than-average probability of contracting colon cancer. Analogously, a person could also be denied employment or life insurance based on similar kinds of group profiling that used arbitrary associations and correlations (generated by data mining), linking trivial nongenetic information (such as the color of one’s car) with sensitive information about one’s genetic data. Furthermore, many people who become identified with these (nonobvious) group profiles will have no chance of correcting any inaccuracies or errors that could easily result from their group identification (because they may have no idea that they have been associated with a group whose existence is unknown to them).

Bioinformatics and the Informed Consent Process in Genetic Research

The process of informed consent used in bioinformatics research involving data mining has also been controversial. For example, it is questionable whether the consent process used by deCODE in getting permissions from human research subjects met the required conditions for “valid informed consent.” Consider that even if the human subjects agreed to have their personal data used in a specific context by deCODE, it is not clear that they fully comprehended the process of how their genetic data could be used in secondary or subsequent contexts (e.g., when it was cross-referenced with information in nongenetic databases). Furthermore, it might not even have been possible for deCODE to inform these subjects in advance about all of the potential secondary uses to which their genetic information could be put in future research (Tavani 2004b).

O’Neill (2002) argues that the informed-consent process is ethically important because it

enables human research subjects to protect themselves against both “coercion and deception.” She also argues that for this to be achieved, the consent process must be open or transparent. But we can reasonably ask whether her “transparency requirement” can be satisfied in research practices where data-mining techniques generate data that can be used in subsequent applications without additional consent from the human subjects affected. Thus, it would seem that the kind of conditions required for “valid informed consent” are extremely difficult, if not impossible, to achieve in cases that involve secondary uses of personal genetic information made possible by data-mining technology in bioinformatics research.

Concluding Remarks

We have considered only one case example – i.e., our brief analysis of deCODE Genetics – to illustrate a recent cyberethics issue affecting personal privacy in the context of bioinformatics research. Of course, numerous case examples could have been devised to illustrate the many different kinds of controversies that arise within the field of cyberethics. However, our main objective in this brief overview of the field has been to identify, describe, and elucidate some of the foundational elements and key principles of cyberethics.

Overview

The term “Cyborg” arises as a short form of “Cybernetic Organism,” which is an entity made up of both biological and technical elements. Initially it was used to describe any system of this mixed type (Clynes and Kline 1960); however, it has more recently been employed for entities where the biology and technology are integrally attached, thereby removing people riding bicycles or wearing glasses from the definition.

To be called a Cyborg it is normally the case that the entity has abilities above and beyond those exhibited by either their biological or technological parts alone. This has possibly come about due to fictional stories in which the cyborg has mental and/or physical capabilities which are far beyond those of humans. A counter example to this is the use of the expression, probably by the media to hype the story line, to describe an amputee who has been given an articulated leg or arm, or a patient suffering from a neurological disorder who has received a stimulating neural implant.

While potentially broader definitions are acknowledged, in this text the common understanding of a “Cyborg” is taken to be appropriate. So the focus here is on humans or animals that are enhanced mentally and/or physically over and above the “norm” with integral technology, rather than where technology is merely worn and/or is employed purely for restorative or therapeutic purposes or even to enhance an individual in comparison with their own problematic state. It has to be pointed out, however, that there is by no means a clear division between enhancement and therapy in this situation.

Before continuing, it is worth pointing out that this entry is concerned with actual cyborgs. Hence, it does not deal with cyborgs in art, in popular culture (such as Science Fiction), or social cyborgs, which are directed toward road or city networks. What follows is a look at cyborgs in different contexts, in particular medicine and sport, with subsequently a discussion of animal-based (rather than human-based) cyborgs,

which can give an indication of what might also one day be possible in terms of humans.

Medicine

Although primarily aimed at restoring an individual back toward their original capabilities by means of replacement limbs or functions, some technologies also offer the possibility of taking things further and extending performance past the original.

There are now many human individuals who exist with the aid of integral technology. This can range from an implanted pacemaker to artificial/replacement hips to implants to assist hearing and even to an artificial heart. As in the latter case, the implant may possibly be merely a holding state, to keep the patient alive until a transplant is available. Conversely, it may be an attempt at either a direct replacement of a malfunctioning biological original or as an aid to try to ensure that the biological original continues to perform its duties reasonably well.

Perhaps part of the cyborg family are some people with artificial legs or arms. For example, the C-Leg system is an artificial leg used to replace a human leg that has been amputated. The leg contains a number of sensors such that, under microprocessor control, the leg can alter its gait to best replicate the natural gate of the user. There is no reason why such a leg could not ultimately outperform the original in terms of speed of operation or power.

As far as artificial arms are concerned, the i-Limb hand is a five-digit hand with individually powered fingers that can be controlled by myoelectric signals generated by muscle movements in the remaining part of the person's limb. A better example in this category perhaps is the work of Todd Kuiken at the Rehabilitation Institute in Chicago (Kuiken et al. 2009). Where an individual has had an arm (or two) amputated, leaving functioning nerve fibers to the arm in place, but no longer useful, then these nerves can be redirected in order to control a replacement bionic arm (or two).

The surgical technique involves grafting some of the nerves, which were originally controlling the amputated arm, to functioning muscles so that these muscles contract when the subject thinks about using their amputated hand. Electric signals from these muscles can then be used to control the artificial hand via the traditional myoelectric route using externally positioned electrodes.

If only the lower part of the individual's arm has been amputated, then muscles higher up in the arm can be used for this purpose. Conversely, if the entire arm has been removed, muscles in the upper chest can be employed, with external electrodes positioned on the chest to monitor appropriate muscle movements in order to translate these signals into control signals for an articulated arm replacement. The first person to benefit from this technology was Jesse Sullivan a power worker who, in 2001, received replacement bionic arms when he had both his original arms amputated at the shoulder following an electrical accident.

Research is currently being conducted by several groups in the area of retinal microchip implantation, to replace malfunctioning visual input in humans. As an example, microchips, which contain up to 5,000 solar cells have been implanted into the back of the eye. When light strikes the solar cells, it is converted into electrical signals that travel through the optic nerve to the brain and are interpreted as an image. The silicon in this way acts as a replacement for a malfunctioning retina. The replacement retina has a diameter of 2 mm. The 2-h operation is done through an incision in the sclera (the white part of the eye), and the chip is inserted into a pocket beneath the retina.

The device displays only black and white images and works best in well-lit rooms, but it is hoped that the addition of more solar cells on the chip will improve results. Much of this technology relies on the ability of the human eye to accept silicon chip implants. Numerous patients have now tested this device over a number of years and all report improved vision. However, at present, this is far from a restoration to anything like normal vision

and is certainly not at the stage of experimentation on supervision incorporating a wider-frequency spectrum.

Other research is more formative and is yet to show similar practical results. For example, a different retinal prosthesis is being developed by a group led by Joseph Rizzo (Jensen and Rizzo 2007). Rather than being positioned near the photoreceptors, the chip will be positioned near the ganglion cells, which send nerve impulses to the brain. The prototype uses a camera mounted on a pair of eyeglasses to capture and transmit a light image to the chip. The light and images are converted into electrical impulses, which are transmitted to the brain along the optic nerve. It has to be said though that this is all rather speculative.

Already well developed and commercially available are cochlear implants. These are surgically implanted electronic devices that provide a sense of sound to a person who is profoundly deaf or severely hard of hearing. A cochlear implant does not amplify sound, but works by directly stimulating any remaining functioning auditory nerves inside the cochlear with an electric field. External components of the cochlear implant include a microphone, a signal processor, and a radio-frequency transmitter. A radio-frequency receiver is implanted beneath the skull's skin. The receiver relays the incoming signal to the implanted electrodes in the cochlea. The implant even now gives recipients additional auditory information, enabling the ability to understand speech in quiet environments. It is quite possible though for the normal auditory sound input frequency range (in humans typically up to a maximum of 20 KHz) to be extended in the future.

Over 150,000 people worldwide have already received cochlear implants, the vast majority of these being in developed countries due to the high cost of the device, surgery, and post-implantation therapy. A small but growing number of the recipients have bilateral implants (one implant in each cochlea). Once an implant is in place, the recipient has to train themselves to recognize the signals now being received via their auditory input, a feat which may involve learning to

understand signals with frequencies not previously entertained.

Another type of implant that is now widely used is that employed for deep brain stimulation. This has, thus far, mostly been used to overcome the effects of Parkinson's disease, by sending electrical impulses into the globus pallidus or subthalamic nucleus regions of the brain. Although the present technology involves the application of a continual stimulation signal, research is ongoing to predict when Parkinsonian conditions (tremors, dystonia) are shortly to occur such that a stimulating signal is only applied to stop the effects before they start.

This research requires accurate modeling of the relevant part of the brain such that a computer is employed to predict what the human brain is going to do some time before it actually does it. The same type of stimulator can be used in constant stimulation mode to overcome the effects of clinical depression, Tourette's syndrome, and Epilepsy; however, the novel predictive technique opens up the possibility not only for the treatment of a variety of neurological disorders such as these but also for its use in a plethora of ways where signals within the brain can be monitored and used to infer what will subsequently be decided by the brain.

Brain-Computer Interfaces

A small number of research groups have experimented with implants positioned in the brain of humans more for communication purposes. Although the humans involved have, in most cases, been in a relatively poor medical condition, the technological potential of such experimentation is possibly much wider than that already discussed.

One line of research has been focused around patients who have suffered a stroke, resulting in paralysis. The most relevant is the use of a brain implant which enables a physically incapable brain stem stroke victim to control the movement of a cursor on a computer screen (Kennedy et al. 2004). Functional Magnetic Resonance Imaging (fMRI) of the subject's brain was initially carried

out to localize where activity was most pronounced while the subject was thinking about various movements. A hollow glass electrode cone containing two gold wires was then implanted into the motor cortex, in the area of maximum activity.

When the patient thought about moving his hand, the subsequent activity was detected by the electrode, then amplified and transmitted by a radio link to a computer where the signals were translated into control signals to bring about movement of the cursor on a computer screen. The subject successfully learnt to move the cursor around by thinking about different hand movements. Eventually the patient reached a level of control where no abstraction was needed – to move the cursor he simply thought about moving the cursor. This could, therefore, be regarded as replacing some of the recipients' original functions or as giving the individual the ability to move the cursor by neural signals alone.

Some of the most impressive human research to date has been carried out using a microelectrode array, consisting of 100 electrodes. The individual electrodes are only 1.5-mm long and taper to a tip diameter of less than 90 μm . Human tests are at present limited to two reported studies. In the second of these, the array was employed in a recording only role (Donoghue et al. 2004). Activity from a few neurons monitored by the array electrodes was decoded into a signal which enabled the recipient to position a cursor on a computer screen, using neural signals for control combined with visual feedback.

The first use of the microelectrode array has though considerably broader implications way beyond the concept of therapy and which gives the best reflection of a practical cyborg to date.

As a step toward a broader concept of human-machine symbiosis, in the first study of its kind, a microelectrode array was implanted into the median nerve fibers of a healthy human individual in order to test bidirectional functionality in a series of experiments. A big difference between this and the studies already discussed is that signals could be both input to and output from the nerve fibers. A stimulation electric current

directed into the nervous system allowed information to be sent to the user, while control signals were decoded from neural activity in the region of the electrodes. In this way, a number of experimental trials were successfully concluded (Warwick et al. 2003), in particular:

1. Extra sensory (ultrasonic) input was successfully implemented and made use of.
2. Extended control of a robotic hand across the Internet was achieved, with feedback from the robotic fingertips being sent back as neural stimulation to give a sense of force being applied to an object (this was achieved between USA and UK).
3. A primitive form of telegraphic communication directly between the nervous systems of two humans was performed.
4. A wheelchair was successfully driven around by means of neural signals alone.
5. The color of jewelry was changed directly as a result of neural signals – as indeed was the behavior of a collection of small robots.

In these studies, there was no therapeutic, restorative need for the implant. The individual's nervous system was plugged directly into the Internet, thereby allowing for the remote control of technology by neural signals alone and also for the input of remote sensory stimulation. Essentially the individual involved had their nervous system extended across the Internet – a true cyborg, a human with integral technology, exhibiting a number of powers not available to regular humans.

Sports

At the present time, some of the physical aspects of cyborgs are starting to raise questions regarding human sporting value judgments drawn, particularly in athletics. It is already the case that the world record time for completing a marathon in a wheelchair is much lower than that for completing the same distance on two legs, but it is difficult to regard the wheelchair itself as being an integral part of the body, hence classifying such individuals as cyborgs is perhaps outside the scope.

What is more pertinent is the use of artificial/ technological legs as a replacement for biological legs. As an example, Oscar Pistorius is a South African double amputee (both his legs were removed from half way between knee and ankle) who competes in sprint races with J-shaped carbon fiber add-ons called the “Cheetah Flex-Foot.” The general ruling from the International Amateur Athletic Federation is that Pistorius and other would be cyborgs can compete with regular humans as long as they do not employ “any technical device that incorporates springs, wheels, or any other element that provides a user with an advantage over another athlete not using such a device.”

Clearly the ruling is a precarious one and opens up arguments as to which differences present an advantage and which do not. For instance, it has been alleged that the “blades” Pistorius uses are longer than is necessary, allowing him to cover more ground in each stride. It has also been claimed that the Cheetahs return more energy per stride without ever becoming fatigued or requiring the same “investment of energy” and that they are not subject to the lactic acid build up that slows down human athletes.

It is anticipated that many other sports will soon face problems of dealing with cyborg participants when they wish to compete with regular humans.

Animals

Nonhuman animal studies can be considered to be a pointer for what is potentially achievable with humans in the future. As an example, in one particular animal study, the extracted brain of a lamprey, retained in a solution, was used to control the movement of a small-wheeled robot to which it was attached (Reger et al. 2000). The lamprey innately exhibits a response to light reflections on the surface of water by trying to align its body with respect to the light source. When connected into the robot body, this response was utilized by surrounding the robot with a ring of lights. As different lights were switched on and off, so the robot moved around its corral, trying to position itself appropriately.

Meanwhile in studies involving rats, a group of rats were taught to pull a lever in order to receive a suitable reward. Electrodes were then chronically implanted into the rats' brains such that the reward was proffered when each rat thought (one supposes) about pulling the lever, but before any actual physical movement occurred. Over a period of days, four of the six rats involved in the experiment learned that they did not in fact need to initiate any action in order to obtain a reward; merely thinking about it was sufficient (Chapin 2004). The same team also carried out studies in which rats, with implanted electrodes, were controlled remotely to negotiate a maze. An operator at a computer terminal could cause the rat to turn right or left at a junction merely by pressing a button.

In another series of experiments, implants consisting of microelectrode arrays have been positioned into the frontal and parietal lobes of the brains of two female rhesus macaque monkeys. Each monkey learned firstly how to control a remote robot arm through arm movements coupled with visual feedback, and it is reported that ultimately one of the monkeys was able to control the arm using only brain-derived neural signals with no associated physical movement. Notably, control signals for the reaching and grasping movements of the robotic arm were derived from the same set of implanted electrodes (Nicolelis et al. 2003).

In another project, rat neurons were separated using enzymes and then cultured/grown on a flat multi-electrode array. The neural culture, a self-contained biological brain, was electronically stimulated via the electrodes (inputs) and its electronic response witnessed on other electrodes (outputs) (Marks 2008). The project involved networking the biological brain with a robot mobile platform. The input (sensory) signals to the brain were solely the signals obtained from the wheeled robot's ultrasonic sensors, thereby giving the brain a sense of distance. The output from the biological brain meanwhile was used to drive the robot around. The overall cyborg, with a physical body and biological brain then learned to move around in a corral without hitting into objects. The research is aimed at understanding

basic functioning of the brain, particularly memory, and hence this cyborg is useful as a test bed for research into diseases such as Alzheimer's disease. It is anticipated that before long, human neurones will replace the rat neurones in this study.

Others

At present, there are a range of other studies and technologies that could be seen, by some, as being indicative of cyborg technology. It is felt to be worthwhile taking a brief look at each in turn.

RFID – Radio Frequency Identification Devices, when employed as implants, certainly can give the recipient a variety of abilities not exhibited by humans. While they do not alter any functions within the human body and are not themselves affected by any bodily activity, when activated they do send a personal identifying signal to an external receiver which can be used to carry out functions (e.g., open doors automatically, switch on lights) for that specific individual without the individual having to press a button or flick a switch.

Magnetic implants – small magnets can be placed under the skin, allowing objects to be magnetically attached to the body. One purpose is for sensory experimentation, in which the movement of the implant in the presence of magnetic fields can be felt by the individual.

EEG – Electroencephalography is perhaps the most studied noninvasive interface, mainly due to its ease of use, portability, and low setup cost. Unfortunately, it is susceptible to noise, requires extensive training, and has relatively low resolution with poor repeatability. A number of groups have used the output from external scalp electrodes measuring EEG to drive a computer cursor or vehicle. Often the process is extremely slow, requires months of training, and is highly unreliable. Although individuals wearing such electrodes can appear “cool” for a media image, especially when linked with the term “cyborg,” the technology is certainly not integral with an individual and it is difficult to claim that the person is doing something that they could not

otherwise do, in most cases a lot more effectively, in an easier way.

Ethical Standpoint

If the application of technology is limited to therapeutic means then there may be a few who grumble, but on the whole this is widely accepted. When it comes to human enhancement, however, the picture is less clear. Surely any individual should be allowed to upgrade themselves if they want, otherwise the all important value of freedom of the individual comes into question. Conversely the upgrading of a few humans could realize a new sect and even, ultimately, a new species with abilities well beyond those of humans. So shouldn't such technological progression be curtailed?

But therapy and enhancement cannot be simply separated with a thick line between them. For example, a new ultrasonic sense could provide a person who is blind with the ability to detect objects and move around much more rapidly on their own and thereby regain dignity. Who could deny that? On the other hand, exactly the same technology in an individual with normal vision would give that person an extra sense. Is it right for some individuals to have more senses than others? But on the other hand, if the technology is available it seems a little stupid to restrict its use to a small group of individuals – particularly if there is commercial gain, with jobs and livelihoods to benefit.

It is apparent that the whole area of cyborgs raises enormous ethical and societal topics that are not at all clear. Even addressing issues as to what animal research is carried out and whether or not human neurons should be cultured in a robot body can stir up a variety of feelings. Historically it is often commercial and military aspects that carry most weight and here the picture is clear that enhancement will take place quite simply because the available technology provides a distinct advantage. At this point in time, as this entry has shown, the age of the cyborg is merely at its beginning, but it is clearly in the ascendancy.

D

Da Vinci Code

Carl Raschke
Department of Religious Studies,
University of Denver, Denver, CO, USA

The title of a novel by author Dan Brown, and subsequent motion picture, that was extraordinarily popular in the beginning of the current millennium. The theme of Brown's thriller was that early Christianity had been a form of goddess worship based on ancient Gnosticism, a "secret" which the Catholic Church had gone for centuries to extremes in order to suppress. While Brown's novel had an equally tremendous impact on the general public's interest in Gnosticism, it was based on highly dubious and largely fanciful historical information that has confused more than illumined responsible research into who the Gnostics actually were.

Description

► [Daoism](#) is the major Chinese autochthonous tradition next to Confucianism. Throughout history, it has played a major role as a philosophy as well as a religion.

Daoism does not fit well into the established Western categorization, which considers philosophy and religion as separate entities; consequently, there has been much debate in China and in the West about the relation of Daoist philosophy of the pre-Qin period (before 221 BCE), also termed "philosophical Daoism," and the Daoist religion, whose first known institutions go back to the second century CE. This entry will consider both, religion and philosophy, as integral parts of "Daoism."

The common ground of philosophy and religion, as well as among the many different strands of religious traditions that considered themselves "Daoist," is the reference to "Dao" as origin of teaching and aim of cultivation and the transmission of knowledge of this Dao. "Dao" 道, literally "way," is conceived in Daoism as the origin and regulating force of the universe and of all being.

Important foundational conceptions of Daoism go back to a short and in many ways enigmatic text of about 5,000 characters, purportedly written by Laozi 老子 in the fifth century BCE: the *Daode jing* 道德經, the *Classic of the Way and its Power*, as A. Waley (1934) translates, or else *The Classic of the Way and the Virtue*, as many other translators render the title.

The history of the booklet is shrouded in mystery. The received version of the text relies on the text commented by the famous scholar Wang Bi (226–249). However, an older version of the text, excavated in 1993 in the Guodian tombs in Hebei, written on Bamboo slips, confirms that in spite of several differences with the received version, the text existed already in 300 BCE.

The *Daode jing* was probably conceived, just like the teaching of Confucius, as a guideline for the ruler to govern well. It proposes that in order to achieve supreme power, the ruler should align himself with Dao.

Dao is a central theme in the *Daode jing* and gives the name to “Daoism.” It is the ontological ground of all being and at the same time the originator and regulator of all being and of all natural processes.

There was something formless yet complete,
That existed before heaven and earth;
Without sound, without substance,
Dependent on nothing, unchanging,
All pervading, unailing.
One may think of it as the mother of all things
under heaven. . . . (ch. 25, Waley 1934)

As ontological ground and origin of all being, Dao embraces all being. This poses an epistemological problem, since anything that embraces all possible being must be “not-being,” in a sense that it cannot have any definable characteristic, because any such characteristic would exclude its opposite and, thus, only “not-being” is able to embrace all being. Dao therefore cannot be described by means of language:

The Way that can be told of is not an Unvarying Way;
The names that can be named are not unvarying names.
It was from the Nameless that Heaven and Earth sprang;
The named is but the mother that rears the ten thousand creatures, each after its kind. . . . (ch. 1, Waley 1934)

Just like Dao cannot be described in words because it transcends any definable characteristic, its functioning cannot be pinpointed to a definite activity and is therefore described as “not-doing” (*wuwei*) in a sense of “not actively

interfering”; however, this “not-doing” entails “nothing that is not done” (*wubuwei*):

Tao never does; Yet through it all things are done. . . . (ch. 37, Waley 1934)

Human beings should strive to imitate this Dao in their dealings with the outer world. The term *wuwei* 無為, not actively interfering, is used also to describe the ideal behavior of human beings and in particular of a ruler. By letting things run their natural course, it was believed that they would by themselves become perfect.

“Kingdoms can only be governed if rules are kept; Battles can only be won if rules are broken.” But the adherence of all under heaven can only be won by letting-alone. . . .

Therefore a sage has said: So long as I “do nothing” the people will of themselves be transformed. . . . (ch. 57, Waley 1934)

As guideline for individual self-cultivation, the proposition of imitating the ways of Dao was taken one step further: The individual should strive to unite with Dao and thus become part of the eternal, which meant to become immortal. Since Dao is not only regulator, but also origin of all being, Daoist adepts sought to “return” to Dao by retracing the process of becoming, by which Dao brought forth being, backward. Where the process of becoming, the change from nonbeing of Dao to being and the 10,000 things, implied ever-increasing multiplicity and complexity, the process of return would imply ever-diminishing complexity, until the adept reaches ultimate oneness in Dao:

Learning consists in adding to one’s stock day by day; The practice of Tao consists in subtracting day by day. Subtracting and yet again subtracting; Till one has reached inactivity. . . . (ch. 48, Waley 1934)

The text of the *Daode jing* always had offered itself to multiple level readings. Its vagueness allowed many different interpretations, and thus, the booklet was venerated and studied by different groups of people throughout the centuries. Its interpreters read it variously as a guide for ruling, as a philosophical reflection on ontology and cosmogony or as an instruction for reaching longevity or immortality.

Its underlying conception that Dao is all embracing furthermore has an exceptional potential for integration of different concepts and ways of thinking and believing.

Thus, in the course of time, many different directions of thought and teachings emerged from this teaching or referred themselves back to it, from immortality seekers and alchemists to war strategists, from philosophers to recluses and monks.

The author of the *Daode jing* is called Laozi. Modern scholarship tends to doubt that he ever existed or that the booklet was put together by one man. However, for more than two thousand years, the name of Laozi has been associated with the booklet of the *Daode jing*, at times as the philosopher who authored the book, at times as the deity who revealed the book.

The earliest references to Laozi we find in the writings of Zhuangzi (369–286 BCE), an important philosopher who is also counted among the Daoists, who relates stories of a meeting between a person called Lao Dan and Confucius (ch. 14 and 33).

About a century later, the philosophical texts *Han Feizi* (ca. 280–233 BCE) (ch. 38) and *Huainanzi* (180–122 BCE) (ch. 11) associate quotations from the *Daode jing* with Laozi.

In 104 BCE, the historian Sima Qian (ca. 145–86 BCE) composed a biography of Laozi contained in his *Shiji*, *Record of the Historian*. This biography relates how Laozi, holding a minor official position in the sixth century BCE under the Zhou dynasty, was disappointed with the government and decided to leave the lands of the Zhou. When he was about to cross the border toward the West, Yin Xi, the guardian of the Louguan Pass, stopped him and asked him to leave some instruction. Laozi thus wrote the *Daode jing* and left it with him. Sima Qian speculates that the Lao Dan praised by Zhuangzi might have been Laozi.

This biography of Laozi became the basis for a rich mythology, developed through the centuries. The myth begins at the “border crossing” – when Laozi leaves for the West. In a text from the first century BCE “The Lives of the Immortals” by Liu Xiang (*Lie xian zhuan*, 77–6 BCE), we

find an elaboration of the theme of going West, where Laozi and the Guardian are portrayed as seekers of longevity.

As of the second century CE, documents from different social environments show that by then Laozi was conceived as a deity. Emperor Huan (r. 147–167 CE) built a palace on the traditional site of Laozi’s birthplace and authorized veneration and sacrifice to Laozi. The *Laozi ming* (Inscription on Laozi) written by Bien Shao in c. 166 CE as a commemorative marker for the site presents Laozi as an embodiment of Dao and also as having the capacity to metamorphose and incarnate at will – often as advisor to the sage kings of China. Texts from a popular environment, like the *Laozi bianhua wuji jing* (“*Scripture on the Transformations of Laozi*”), document that millennial cults of the second century CE believed in Laozi as a messianic savior.

In Sichuan, the sect of the Celestial Masters based their teachings on an alleged revelation of Laozi to their leader Zhang Daoling in 142 CE and revered Laozi as *Lao jun* (Lord Lao) or *Tai Shang Lao Jun* (Lord Lao Most High) as their highest deity.

This sect established the first known social organization of Daoist religion.

Followers were organized into 24 dioceses, each headed by a priest called *jijiu* (libationer). Priests of this sect to this day live in the family and are not celibate. Adherents had to pay a tax of five bushels of rice; thus, the sect was also called five bushels of rice sect (*Wudoumi dao*). Another designation of the Celestial Master’s sect was *Zhengyi dao* (Way of Orthodox Unity), and under this name it continues to exist today along the monastic *Quanzhen* (Complete Perfection) sect as one of the two main religious organizations of Daoism.

The Celestial Masters sect spread from Sichuan first to northern China and then in the fourth century CE also to the south. There they met a different tradition, which claimed its origin in “Dao”: longevity seekers and alchemists, related to the ancient traditions of the “*fangshi*” (Masters of Esoterica). Furthermore, also Buddhism had gained a foothold in the area since the end of the third century. From the interplay of all these

religious movements in the Jiangnan area of southern China emerged two important traditions, based on scriptures allegedly revealed by immortals: the *Shangqing* (Highest Clarity) scriptures between 364 and 370 CE and the *Lingbao* (Efficacious Jewel) scriptures around 400 CE. While originally competing, these and other traditions were eventually integrated into a hierarchically organized Daoism, which comprised ritual practice as well as individual self-cultivation, often with the aim of reaching longevity. The growing scriptural lore was organized in a proto-canon reflecting the hierarchical organization of the developing religious organization. Competition with Buddhism and also Confucian teachings for influence in the imperial court led to further consolidation of originally disparate movements, and by the Tang dynasty (618–906), Daoism became the official state religion.

Yet, even institutionalized as a state religion, Daoism remained a rather open system, interacting with Buddhism and different local cults and co-opting elements from both.

Daoism during northern (960–1127) and southern (1127–1279) Song dynasty enjoyed imperial protection of several emperors. In 1119 CE the carving of the blocks for the first print edition of the Daoist canon began (Schipper and Verellen 2004: 28).

This period also saw the rise of “inner alchemy,” techniques of meditation which aimed at creating longevity by interiorizing the alchemical process. In 1170, Wang Zhe (1113–1170) founded the *Quanzhen* sect. He specialized in “inner alchemy,” and his focus on meditative practice entailed the establishment of celibate monastic communities. The *Quanzhen* sect survives today as monastic Daoist tradition.

Quanzhen Masters obtained imperial patronage in 1197, and the sect grew in importance during the first part of the rule of the Mongolian Yuan dynasty (1271–1368). However, acrimonious debates with Buddhists led emperor Kublai Khan (1215–1294) to turn against Daoism and in 1281 order the destruction of the Daoist canon. The following Ming dynasty (1368–1644) changed the course of Daoism’s development again, favoring Daoism of the *Zhengyi* tradition.

The last dynasty to rule China, the Manchurian Qing dynasty (1644–1911), saw increasing contacts with the West, from the early Catholic missions to the gunboat policy and the Opium Wars. The apparent weakness of China in front of the Western powers led many Chinese to study Western culture, science, and technologies and to reject traditional Chinese culture and values.

The fall of Imperial China in 1911 intensified this trend; the Nationalist as well as the Communist government promoted “rational” and modern culture; Daoism was relegated to the field of superstition; it was considered reactionary and suppressed together with other religions. The height of suppression happened during Cultural Revolution (1966–1976).

Religious policies changed with China’s opening and reform policies after 1978, and as of 1980, Daoism has come to light again, with a fast growing number of renovated and new temples and official representation through the “Daoist Association of China” (*Daojiao xiehui*) as one of the five recognized religions of China. In addition, Daoism has seen some internationalization, carried originally mainly by practices like *Qigong* or *Taijijuan*, which have become popular in the West. Since the 1970s, Daoist temples have been established in some Western countries, in particular in the USA, and more recently Daoist Associations have been founded in several countries, like in the UK (1996), the USA (2000 and 2004), Spain (2001), Switzerland (2007), and others.

With China emerging as a major global economic power, growing self-confidence leads also to regained confidence in its autochthonous culture, in traditional Chinese values and thinking. After the promotion of New Confucianism in the first decade of the twenty-first century, also Daoist philosophy is praised again by some influential academics in China as a possible source of inspiration for the solution of the most pressing problems of humanity – in particular the ecological crisis.

Self-Identification

While, in the twentieth century, Daoism was denigrated and even persecuted as a “superstitious”

religion in China, a British scholar, Joseph Needham (1900–1995) in his monumental work *Science and Civilisation in China* (Needham 1956) claimed that Daoism was foundational for China's ancient scientific development. While this particular theory was refuted later by the American scholar Nathan Sivin (1995), Needham's theory that associated Daoism with science remained influential, especially after its translation into Chinese was published in 1990.

One important impetus for Sivin's critique of Needham's theory was that since the late 1960s a big change had occurred in Daoist studies. Where previously scholarly accounts of Daoism focused on ancient Daoist philosophy and ignored the Daoist religion that had developed after the first century CE, Daoist studies after the 1960s focused on this Daoist religion, and eventually the scholarly vision of Daoist history was rewritten. Where Daoism previously, also in the writings of Joseph Needham, designated a rather vague philosophical trend, it now was recognized as a religion associated with a definable social group, the Daoists.

Sivin argued that most persons accredited with important developments in the history of science in China were officials, but not Daoist priests or monks.

Since the beginning of the twenty-first century, the question of an association of Daoism as philosophy and as religion with science has been reopened by Chinese Daoist or philo-Daoist academics. These intellectuals claim that Daoism – as it is expressed in the *Daode jing* or the *Zhuangzi*, but also in the alchemical teachings and writings of the seekers of longevity of later Daoists – is science.

They emphasize that Daoism has a “scientific” outlook because it emphasizes the importance of observation of natural processes, and they point out the scientific contents and achievements in Daoist writings on medicine, alchemy, astronomy, cosmogony, and cosmology.

Compared to Needham and the earlier discussion on the relation of Daoism and Science, there is an important new element: the religious dimension of Daoism is explicitly recognized and valued.

With a globalizing world facing crises like the ecological crisis, Western culture has been criticized widely as part of the problem. Asian cultures, China in particular, are regaining economic power and influence on the world stage and are searching in their own heritage for solutions to the pressing problems of the twenty-first century.

Daoism and Science are discussed in three important contexts:

First, Daoism is promoted as autochthonous Chinese way of thinking with aspects and elements that can be called scientific. Daoism is therefore proof that Chinese traditional culture did develop scientific thought, challenging the assumption that Western civilization is the only source of scientific thought (Jiang Shen and Tang Weixia 2002/2010).

In response to the global ecological crisis, scholars and Daoists have emphasized the potential of Daoism, with its special affinity to and concern for nature, to contribute to find solutions for this crisis. This debate was initiated by scholars at an international conference in Harvard on Daoism and Ecology in 1998 (Girardot et al. 2001).

Acknowledging that in order to find solutions for a global world, far-reaching cultural changes will be needed, Daoism is hailed as a way to combine spirituality or religion and science, thus overcoming the separation of religion and science current in the Western cultural sphere, which is deemed dangerous because it neglects not only spiritual but also ethical and moral dimensions (Hu 2006).

A prominent advocate of this connection between Daoism and Science is Jiang Shen, professor at Shandong University and director of the Institute of Religion, Science, and Social Studies (IRSSS) founded in 2002 at Shandong University, which offers also a doctoral program “Daoism and Science” and runs a research project “Daoism and Science: Past and Present” and a state-planned research project called “The History of Science and Technology in Taoism.”

Another major promoter is Hu Fuchen, professor at the Institute of Philosophy at the renowned Chinese Academy of Social Sciences (CASS) in Beijing. He proposes a “New Daoism,” which he presents as a strategic ideological possibility for

the global world, for all humanity, to address the most urgent problems of our planet, many of which have been, in his view, ultimately caused by developments driven by Western values (Hu 2006). This New Daoism movement has to be considered not only as an answer to Western culture but also as an answer to the New Confucianism movement, which has gained much adherence and attention in China since the end of the twentieth century.

The claim that in Daoism religion and science are harmoniously united plays an important role in the promotion of New Daoism:

The unlimited transcendent ontology nature of the Dao can be regarded as the ultimate religious belief and the Dao can be seen as the converging point for rational science and philosophy and non-rational religion. This is of unrivalled significance to the development of human civilization. (Hu 2006)

It is not quite clear yet to what extent this movement, which originated in a rather academic environment, will be supported and promoted also by the Chinese Daoist Association and by wider groups of Daoist practitioners.

Characteristics

Daoism is an autochthonous Chinese tradition and religion. It differs from Confucianism in as much as its teaching focuses on the ultimate origin and rule of being and on individual cultivation, whereas Confucian teachings tend to focus on the social community. Furthermore Daoism has many explicitly religious elements, like the veneration of a multitude of deities, rigorous self-cultivation in order to transform the individual being, and a strongly developed ritual and liturgical practice.

In these respects, Daoism shows some similarities and overlaps with Buddhism. However, Daoism differs from Buddhism in the conception of transcendence and in its soteriology. Where Buddhists seek salvation in Nirvana, which implies liberation from the cycle of birth and death and transcending this world of being, the aim of Daoist self-cultivation is to unite with Dao, a return to the origin of all being. Daoism

conceives of the ultimate as immanent; Dao is the origin, ontological substance, and rule of all being, and salvation lies in uniting with this origin of being.

Sources of Authority

The sources of authority of Daoism are firstly the pre-Qin dynasty writings of the Daoist philosophy and religion, in particular the *Daode jing*, but also the *Zhuangzi*.

These ancient texts have been a reference and authority for more than two millennia not only in circles of religious adepts but also among students of philosophy in China.

Their authority derives mainly from the ancient origin and the status as a classic. The classics were considered as repository of knowledge and ultimate truth.

Historically speaking, Daoism has seen many texts appear that claimed to have been revealed by various deities. These generally gained authority among the adherents that believed in the particular deities – often based on local preferences. One important argument throughout history to legitimize newly revealed texts was the claim that they originated in the distant past, but were hidden in the heavens until the time of revelation.

In the contemporary discourse, which different from the past involves intercultural and global elements, there is an additional emphasis on the fact that these texts represent the autochthonous Chinese tradition in opposition to the Western culture and to the fact that they do show some convergences with modern Western scientific concepts and attitudes. In the context of the latter discourse, the fact that they are compatible with conceptions of science, also the writings of later Daoists on medicine or alchemy, like Ge Hong (283–343) or Sun Simiao (581–682), are at times cited as authority.

For religious adherents and practitioners of Daoism, in addition to the ancient texts, also the teaching of the masters, often personal masters and those of their lineage of teaching have much authority. Transmission of teaching, truth, and

Dao through personal masters in a master-disciple lineage has been an important element in Daoism since ancient times and continues to be of importance for religious practitioners.

Ethical Principles

Dao, origin and regulator of all being and of all natural processes, is considered as good; however, it is beyond conventional human concepts of good and bad. The major ethical principles expressed in the classics of Daoism are based on the concept of emulating the Dao, which implies also to emulate the characteristics of Dao. Of particular importance are being soft, yielding, and not interfering in the natural processes of life. Since Dao is origin and regulator of nature, ethics include respect for nature and the noninterference in natural processes. Living and acting in accordance with nature are considered as good, whereas forceful striving of all kinds, including the strife for knowledge and profit, is considered detrimental for individual life and society.

Key Values

The key values of Daoism are the values derived from characteristics of Dao. Of particular importance is the concept of naturalness, letting things follow their natural course without forceful interference. Along with this comes a mistrust in the manmade culture, including wisdom and knowledge, conventional morals, and selfish longing for profit and gain. Furthermore, Daoist values emphasize female attributes, like being yielding and nurturing, which derive from the concept of Dao as mother of all being.

Conceptualization

Nature/World

Dao brought forth one, one brought forth two, two brought forth three and three brought forth the ten thousand things. . . . (Daode jing 2011 ch. 42)

Daoism conceptualizes nature and the world of being as evolved from Dao, in a progressive division from an original one into increasing complexity. Therefore, Dao is ontological substance of the world and nature, and the world ultimately partakes in Dao. In this concept, Dao represents original oneness; two represent the two opposing forces of Yin and Yang, variously defined as sunny and shady side of a mountain, male and female, light and dark, or, in another interpretation also, Heaven and Earth. Dynamic interaction of these two opposing elements then creates being and regulates all natural processes. All being, nature as well as human beings, emerged from Dao. Nature preserves its original nature, which is Dao, better than human beings because it is not influenced by feelings and cognition or by human morals and manmade conventions.

Human Being

Like all other being and the whole world, human beings are brought forth by Dao. Yet, in all ancient Chinese philosophy, human beings are conceded a special role in the world, since the realm of man is conceived as a third fundamental realm, in addition to the ones of heaven and earth.

In addition, Daoism shares with other ancient Chinese ways of thinking the conception that the human being is seen as a microcosm, which corresponds to the macrocosm of the universe. This conception finds its expression in Daoism in a conception of the human body as a landscape, the so-called inner landscape, inhabited by deities, which correspond to stellar deities (Pregadio 2008:75f).

Life and Death

Daoism maintains that all life is brought forth by Dao. Dao is life creating and life sustaining. The interpretations of death vary in the early phase of Daoist philosophical thinking. Where the *Daode jing* seems to advocate long life and immortality and contemporaneously depict death as something to be avoided, *Zhuangzi* in many of his anecdotes relates life and death as parts of the natural process and advocates a mystic experience that goes beyond valuing life and fearing death. However, since the earliest times, seekers

of longevity and immortality called their goal of cultivation “reaching Dao,” interpreted as avoiding death and reaching immortality in this world by uniting with the eternal source of life.

Knowledge

Daoism regards knowledge as negative or at least as something associated with low stages of spiritual cultivation. Knowledge implies distinctions and multiplicity, and the aim of self-cultivation is to overcome distinctions and multiplicity to return to the original unity of Dao. Epistemologically, Dao cannot be grasped by knowledge, but only by “discarding knowledge” (*Daode jing*, 2011, ch. 19) and returning to natural simplicity, since Dao is beyond distinctions.

Dark Energy

Russell Stannard

Department of Physics and Astronomy,
Open University, Milton Keynes, UK

So-called empty space possessing energy. It is believed to arise from the continual popping into existence of virtual particles - a process permitted by Heisenberg's uncertainty principle. We do not see this energy, and for this reason it is called dark energy. However we do see its effects. It produces a repulsive force. This force is causing the distant galaxy clusters to accelerate away from each other as the universe expands.

[Idea of Holy](#)

From a historical point of view Rudolf Otto's work *Das Heilige* (*The Idea of the Holy*), which appeared in 1917, is one of the crucial points of transition in European thought about revelation and alterity. It could be argued that conceptually and in argumentative style it laid basis for much of what followed. Martin Jay (2004, Chap. 3) has noted that Otto's body of work in general and *Das Heilige* in particular is embedded in the tradition that struggled to find in religious experience a source of knowledge and belief that could supplement the full blown rationalism of modern empirical and critical philosophies. To do just that, Otto found inspiration from the examples of concrete religious experiences in non-European cultures. The philosophies of Friedrich Schleiermacher and Johann Jacob Fries were also central to his formulation of the lineaments of a new theology.

In *Das Heilige* Otto held fast on the experiential, in some sense even irrational, dimensions of religion. These dimensions were ignored even by

neo-Kantianism which was very vibrant at the time. Even though Otto praised Immanuel Kant he simultaneously saw that only Schleiermacher was able to get rid of the Enlightenment rationalism which in Otto's eyes left humanity at a loss. The Enlightenment rationalism had, while claiming to have proved the existence of God, extinguished the *sensus numinus* (also *das Numinose Gefühl*). *Sensus numinus* for Otto was the essential spirit of any religion, and it was something different from intellectual perception of some metaphysical thing or observance of ordinances, as philosophers were used to argue. The recovering of this dimension of religion was Otto's fundamental mission.

Sensus numinus is the experience of the wholly other (*das Ganz Andere*) in fear and trembling. Otto's thinking stresses the categorical difference between human and divine. Concept of the wholly other tries to capture this point in the same manner as Kierkegaard's "infinite qualitative difference" of the divine as the "truly 'mysterious' object that is beyond apprehension and comprehension not only because our knowledge has certain irremovable limits, but because in it we come upon something inherently 'wholly other,' whose kind and character are incommensurable with our own." Otto was also able to anticipate the critique of subjectivism that broke out later during the Weimar period. For Otto *Numinous* is something that is felt as objective and outside of the self.

The experience of the numinous has a double structure. It is the same structure that the object of this experience (*mysterium*) has. First of all the object is a *mysterium tremendum*, an object that is faced with fear and awe. And in this aspect the *mysterium* is at the same time more fascinating and interesting than any other object. In this aspect it is *mysterium fascinans*. This double structure, the "strange harmony of opposites" that Otto opens up in his work, is for him the most central and at the same time the most peculiar thing in the whole history of religions. With the close analysis of this structure Otto draws the dynamic of the history of religion in a global scale.

The *mysterium tremendum* has three further elements that Otto investigates more thoroughly

in his book: (1) Shuddering (*das Shauervollen*), (2) Majesty (*majestas*), and (3) Energy (*energicum*). The element of *Das Shauervollen*, which at first shows itself as strangeness, shuddering, and demonic threat, changes with the cultivation of experience to religious and mystic awe. In this element *numen* is seen as absolute non-approachability. The element of *majestas*, or complete pre-eminence, produces the *Kreatur Gefühl*, the feeling of one's insignificance, which is the basis for religious subservience. The living aspect of *numinose* is seen in the *energicum*, which is expressed symbolically as passion, will, power, and activity.

In the introduction to the English translation of the *Das Heilige* from the 1923, Otto made it clear that his argument is not as one sided as it first seems to be or as dialectical theologians had argued. His translator John W. Harvey described this by saying that Otto is not open to the critique of isolating the transcendent Otherness because "God is not for him, so to speak, *wholly* 'wholly other.'" Even though other "is *felt* as objective" the viewpoint that someone (subject) is doing the feeling opens up. This shows how deeply Otto is still connected to the neo-Kantian framework, while the development of his ideas, when seen in the light of the central findings of his work, points toward a direction that goes well beyond neo-Kantianism.

In *Das Heilige* Otto goes on to argue that the Holy is an a priori category. In one sense we might read this as a response to the full rationalization of the Divine in the work of Hermann Cohen, the famous neo-Kantian Jewish thinker. Otto seems to be reaching for the original project of Kant who was famously trying to make room for faith through reason. For Otto, Kant was not able to save the finite perception of the infinite and that is why he needed the help of the work of Schleiermacher and Fries, who both tackled the problem of the subjective "inkling" (*Ahnung*) of the Divine.

But this is the very point the critics quickly exploited. Either the divine is genuinely other (*the wholly other* as the most central of Otto's findings stated) and in this sense the possessive experience of the self cannot capture it at all, or it is not really other in the end. Already in 1929

Friedrich Karl Feigl formulated the problem by saying that "either God is in some absolute sense 'wholly other,' and we cannot experience or say anything about him, *including that He is wholly other*, or we experience something of God, which means God's essence cannot be determined as 'numinous.' *The numinous as category* – whether 'category' is understood in transcendental-logical or with Otto a psychological sense – is a *contradictio in adiecto*." Leo Strauss had made the similar argument in 1923. The point was clear that with the concept of the wholly other Otto was pointing beyond his own premises and this was why Strauss saw it praiseworthy.

Data Structure

Linda Sherrell

Department of Computer Science,

The University of Memphis, Memphis, TN, USA

A data structure may be a built-in programming construct such as an array or simply a term corresponding to the manner in which information is organized. The idea is that a data structure is capable of holding multiple items. Some authors define a data structure to be only those frameworks that are implementation dependent (e.g., the array and the linked list), whereas others define a data structure to be implementation independent (e.g., a stack or a queue). Here, we define a data structure to be an implementation of an abstract data type. In other words, the data structure is a usable form of an ADT.

Death

Scientific/Biological-Medical Dimensions

From a biological and medical perspective, death is as complex and mysterious as life. Death is neither the absence of life nor the second of two mutually exclusive categories: life and death. There is not a sharp distinction between life and death at any level of organization from cell to tissue to organ to whole person. Almost all definitions of death, like all definitions of life, fail because of exceptions. A four-cell embryo of a human being is considered clinically alive, that is, not dead, even if frozen. In some religious traditions, these four cells are even considered to have personhood, which means when the cells die a person dies. In other religious traditions, a human embryo is not a person who can die because life is conferred only at the time of birth or at the time of the baby's first breath. Clinical death, no matter how it is defined, is not the same as legal death, which is determined by law. Under ideal circumstances legal death is pronounced by an authorized medical practitioner or coroner, who signs and then issues a death certificate. Under certain very unusual

*Jay R. Feierman has retired from University of New Mexico

circumstances, death of a person can be determined legally even in the absence of a body.

Imagine a situation in which an adult human being, who has massive brain damage from an automobile accident, is brought into an Emergency Department of a hospital. Basic bodily functions can often be “maintained,” with or without the aid of a mechanical respirator. The patient’s heart is beating, the liver, kidney, and many other bodily organs are working. The body remains warm. If at such time it is determined that there is no demonstrable electrical brain activity in the cerebral cortex on an electroencephalogram (EEG) and the patient does not respond to any type of stimulus, upon the agreement of usually more than one physician in complex cases, the patient can be considered “brain dead.” Depending upon the legal jurisdiction, such a patient might be considered legally dead and transplant organs could then be “harvested.” However, there are lots of moral and end of life ethical issues at this point including actions that deliberately end another human’s life (euthanasia.) The issue gets even more complicated clinically, morally, and legally when persons appear to be alert but are in what is called “persistent vegetative states” (Caplan et al. 2006).

Human death can have many causes. Physicians and coroners categorize the causes of human death into one of four categories: (1) “*natural*,” which includes disease, (2) *accident*, (3) *suicide*, and (4) *homicide*. In some cases, the cause of death can only be listed as “unknown.” The causes of human death vary across time and across nations. Within some nations, there are large differences in frequencies of the causes of death depending on age, sex, racial, or ethnic origin. Infectious diseases – especially malaria, tuberculosis, and AIDS – are the primary causes of human death in the developing world. All of these illnesses are exacerbated by malnutrition. The primary causes of human death in the industrialized world are heart disease and cancer both of which are affected by lifestyle issues and choices. Even if the cause of death is not attributed to anything discussed above, human beings eventually die “naturally” from single or multiple organ failure in senescence.

In any species, including human beings, death of an individual, from whatever cause, is a part of the continuation of life. Were there no individual death there could not be evolution of life by natural selection. Without natural selection, species, including the human species, could not adaptively configure to changing environments. The average age at death, which takes such things as infant mortality into consideration, has steadily risen in the developed world based primarily on decreases in infant mortality and modern health care. In the developed world, life expectancy, which is the number of years of life left at a given age, is always lower for males than for females. This number has varied over historical times and varies today across different countries.

Death can occur by *natural means*, which includes the result of disease. Many of the diseases that kill human beings today in middle and old age in the developed world would not have been factors in human mortality in prehistoric time when most humans did not live past their 30s. The average human life expectancy at birth in the world today is in the 60s. In the developed industrialized world, life expectancy at birth is extended another 10 or 20 more years (Lopez 2002). When death is caused by disease, there is sometimes a point in time in which further treatment aimed at a cure for the disease is no longer possible. Many patients at this stage receive what is called palliative care usually in a nursing home, a hospice, or at home. The objective of such care is to allow the person to die with dignity with a minimum of suffering.

One of the most curious things about human death is that although it is almost always avoided, some human individuals, like individuals in several other species such as bees, kill themselves as a result of their own behavior and for a variety of reasons (Lester 1992). If the behavior is intentional, rather than accidental, in human beings this act is called *suicide*. Some definitions of suicide require that the individual taking his or her own life be aware that he or she is going to die as the result of his or her actions. This is probably not the case in a bee who dies for the good of the colony after stinging someone. However, self-awareness of death prior to the behavior that

ends one's own life is not as important from the biological and evolutionary perspective as the actual life-ending act and its consequence. From an evolutionary perspective, it is difficult to understand how suicide, especially in humans, could have evolved in the context of natural selection.

An evolutionary explanation of human suicide is possible through kin selection theory (de Catanzaro 1981). Human individuals, like stinging bees, would kill themselves for a potential benefit that could accrue to their kin. There are more of one's genes in one's kin than there are in one's self. Human persons who do kill themselves are rarely happy and successful. They are often old, sick, suffering, and utilizing the family's limited resources. When younger they frequently are suffering from psychiatric disorders, most commonly depression and substance abuse or dependence. An exception is China, where suicide is more common among women, especially young rural women (Canetto and Lester 1995). Across nations, and for reasons that are not understood, there is an inverse relationship between homicide and suicide rates. In addition, measured average intelligence correlate positively with the rate of suicide and negatively with the rate of homicide (Templer et al. 2007).

Homicide is being deliberately killed by another member of one's own species. A common type of homicide is infanticide, which is present in a number of species, including primates and including human beings (Hausfater and Hrdy 1984). Among mammals, the only two species in which males live in patrilineal, male-bonded communities, and in groups deliberately kill other males in other groups over territorial disputes are human beings and chimpanzees. The chimpanzee is our closest living relative with whom we last shared a common ancestor about 6–7 million years ago. Ironically, homicidal behavior does not occur at all in our second closest primate relative, bonobos (Wrangham and Peterson 1996). The demographic characteristics of who kills whom among human beings is predicted quite well by evolutionary theory (Daly and Wilson 1988). In some human societies, the state or those persons who govern, with or without the consent of the people, kill members of the

society who transgress certain laws or violate certain moral principles or in nondemocratic states, threaten the continuance of power of those currently in power. Despotic regimes have also engaged in genocide in which men, women, and children of the out-group, defined in various ways, have been slaughtered in mass and then disposed of in inhumane ways.

In all societies, *accidents* are a major cause of death. According to the United States National Vital Statistics Report (2010) and for all ages, after heart disease, cancer, stroke, and chronic lower respiratory disease, accidents are the next most common cause of death. Motor vehicles are the primary means of accidental death with unintentional poisoning and falls coming next. However, in most of the developed world, for persons in their teens and 20s, accidents are the leading cause of death followed by homicide and suicide. At that age, natural causes of death are rare.

Compared to any other extant species, humans bury or cremate their dead in ritualistic ways. There is no human culture known in which other than in some extenuating circumstances, such as warfare, the dead are allowed to simply stay in place where they died. However, the same has been seen with our closest living relative, the chimpanzee. Females in the wild have been known to carry juveniles who have died with them for several days. There is some evidence that *Homo neanderthal*, our nearest known human relative who became extinct about 30,000 years ago, buried their dead and placed flowers that left evidence of pollen upon the bodies.

As a summary of human death, Mark Graves (2008) equates the life of a person ending when a human system ceases to have effect. He breaks death down into several components: "Physically, when decomposed. Biologically, shortly after death when all cell function ceases, such as brain death. Psychologically, when autonomous sentience-response-animation ceases, such as brain death. Culturally, when no cultural system responds to the person, which may occur before or after individual death. Transcendently, a person may never live, or if continued in the interpretation of the community, never die."

Anthropological Religious Dimension

Religious studies have often pointed to a strong connection between death and religion. It could even be suggested that religion emerges as a result of “death management,” or a social form aimed at coping with the problem of finitude. Some studies deduce the need of a “terror management” function deriving from the unique human awareness about the inevitable end (Becker 1973). Religion appears better suited than other social structures to provide fitting answers to this demand. This theoretical approach probably puts too much weight on death perception and fear, and, as a consequence, builds a case for functional religious coping that is debatable. Indeed, an alternative explanation could invert the order of variables: it would be religion – or at least some religious expressions – that confers a particular salience to death, eliciting a greater awareness of its risks and threats (judgment, hell. . .), which otherwise could be ignored or perceived as less threatening and distressing.

In any case, the suggested link is evident when the historical record of world religions is reviewed under this light. Even if not all religions appear as related in the same way and intensity with death, in most cases, many religious forms emerge as trials to deal with death-related anxiety. Social systems theory furnishes an interesting – always functional – approach to the suggested link. Luhmann explains the function of religion in terms of “management of residual contingency,” or the unavoidably negative and unmanageable aspects of individual and social life (Luhmann 1977). Death clearly applies in this case, since there is no way, through “technical treatment,” to avoid that “contingency.” This theoretical approach does not preclude other “functions of religion”: religion is not confined to “death management.” Furthermore, the functional approach appears as somewhat reductive and unable to highlight important aspects of religious mind and behavior.

In any case, it can be justified, from a methodological perspective, to try to understand religion from the point of view of “death management,” and to qualify the beliefs and behavioral system so built as dependent in good

measure from that pressing need. The historical testimonies supply several strategies to cope with death in religious terms.

- In some cases, no direct involvement of religious ideas and practices with death is the rule; the morbidity associated with that negative experience is concealed and its definitive “solution” postponed. A paradigmatic case is offered by ancient ► [Judaism](#). Religious faith in this case served to protect life and to ensure its right length and enjoyment, not to “overcome death,” which was left to an indeterminate time and a future revelation.
- Death is the beginning of a “long journey,” a process of reconstruction of a new life, more or less connected with the former one. Ancient Egyptians developed an elaborate “guide” disclosing an ► [afterlife](#) universe that prolongs the proofs and struggles of present life. Many archeological remains in different cultures express that sense of an almost symmetry between both lives that death separates.
- Death as a “return to the origin,” or as a regression to an undifferentiated time and world. Initiation cults and primitive religious forms point to this structure, conceiving life as a cycle, and death as a new origin, in a different dimension, evoking nevertheless better or not yet satisfied possibilities. In a similar way, death means the end of a state of painful “separation” and the possibility of everlasting unification (Eliade 1957/1987).
- Death becomes another link in the long chain of life. This is characteristic of Eastern religions, like Hinduism and Buddhism. Life and death become closely entrenched through dynamics of *karma*, a link calling nevertheless to a break and definitive interruption.
- Death as a condition of possibility of a process of “redemption” or human reconstruction. This is the case for Christian representations, in which life is seen as limited and negatively conditioned, and death means the end of that imperfect state, and the beginning, sometimes through ways of purification, of a full life with plenty of joy.

Religious death management includes – besides beliefs about afterlife – practices aimed

at expressing deep expectations and representing a state of transition and social transformation. Most religions perform funerary rituals at different stages: to accompany the burial or cremation of a dead person, to intercede for her, or to remind us of her presence or ask for her assistance. The almost universal character of such rituals reveals a constant concern about the need to fill the gap left by the deceased person and to recompose the social harmony disrupted by such perceived absence (Hertz 1907/2004). These rituals have been seen as “rites of passage,” necessary to assume a new awareness and to adapt to a new social frame, after the absence of a member, which represented a link in the system, a knot in the net. Inversely, some ► [rites](#) of passage or social initiation are described in many religious settings as ways of “dying” from a former life and being born into a new one. In all these practices, a similar pattern can be revealed. Religion helps to dynamize communities despite the disrupting effects of death; and pushing for transition and restabilization despite big changes in the life cycle for individuals and collectives alike.

Beyond particular religious beliefs and practices, a more abstract principle can be perceived in the described link. Religion can be thought of as operating in a binary communication code – as do all social systems – that distinguishes between immanence and transcendence, between profane and sacred. Such a distinction knows other “modalities”: between damnation and salvation, between relative and absolute, or between death and life.

A religious modality can perform a type of linkage among several of these distinctions: transcendence with salvation, with absolute, and with eternal life, or with overcoming death. In this representation, death becomes an important element in the semantic that constitutes the religious code; however, it is not the central one, or one providing more “semantic intensity” or meaning. The distinction life-death appears as one helping to extend the core of a potential “religious grammar,” supplying a further explanatory element and broadening its semantic meaning. In any case, the distinction between life and death appears as so radical, as so fundamental or original in human

cultural origins, as to evoke or even become contiguous with the most radical ways of thinking. It provides a very powerful symbol that is able to inspire reversed versions – from death to life – and a symbolic universe born from the absence and void that death induces.

The possible modulations of religious grammar are manifold, as can be confirmed in the plurality of religious traditions dealing with death, and placing it inside their respective “code.” Each religion loads “death” with different meanings, corresponding to the position this concept finds inside each religion’s own code. Furthermore, inside a religious tradition, significant nuances – and sometimes contrasting values – positive versus negative – are perceived between more mystical perceptions of death, and more ascetic or worldly orientations.

Religion is not the only way to deal with death, and religion is not established only – or predominantly – in relationship to death. To be sure, other means compete to fill that function, especially in more secularized societies. Even if some evidence points to slightly better results with ► [religious coping](#) than with alternative means to allay death anxiety (Vail et al. 2010), under any circumstances it can be said that religion provides the only “program” for coping with death. Secular therapeutic, meditative, aesthetic, and life-fulfilling resources appear as clearly “functional” in this new context, lacking more pervading religious references. By the same token, religion in advanced societies does not reduce its scope to “death terror management,” since most religious forms today point to intensifying life experience, instead of “preparing for a good death.”

Another important point to consider is in which measure religious beliefs and behaviors reduce the weight of death and its [dys-] function regarding many aspects of life. Since religious beliefs usually reduce the negative burden of death, thereby several consequences can be expected in human behavior. This predictable effect can have positive and negative consequences. In the positive side, a lessening of the extent of death’s retroactive pressure could trigger greater generosity and altruistic attitudes, even to the point of risking one’s own life for

the benefit of others. Life expectancy and enjoyment could become a factor determining selfish behavior, since fear of death could deter “spending time” on other people’s interest. The dark side of this principle – from a biological perspective – points to forms of fanaticism that leads to extremes of martyrdom, or still worse, of aggressive religious imposition, and suicidal attacks. In any case, both tendencies appear rather confined in some “religious niches” of the most intense forms of religiosity, and the empirical evidence does not always validate that general expectation.

Death clearly appears as ambivalent in most religious mentalities: as a negative reality, corresponding to its more “intuitive” effects of finitude and social disruption; and as a step opening the way to positive future developments, in accordance with “less intuitive” perceptions, born nevertheless in powerful symbols of everlasting life and longing for complete human flourishing.

Deep Brain Stimulation

T. M. Kinfe and Jan Vesper
Department of Neurosurgery, Centre of Neuromodulation, Heinrich-Heine University Hospital, Düsseldorf, Germany

Related Terms

[Functional stereotactic neurosurgery](#)

Description

Nowadays functional stereotactic neurosurgery, more precisely, deep brain stimulation (DBS), has gained widespread acceptance as a treatment modality for movement disorders, pain syndromes, epilepsy, and some neuropsychiatric disorders.

There are several developments which have pioneered this technique over the last and next-to-last centuries. First, one of the cornerstones is the breakthrough work from Sir Victor Horsley and Robert Clarke in 1908. Both introduced a new method to implant a needle or a probe into subcortical structures accurately using a Cartesian coordinate system. They first used their new tool in animal models to study lesioning effects of the cerebellum.

The conferment into humans was compassed in 1947 by the neurologist Ernest A. Spiegel and the neurosurgeon Henry T. Wycis at Temple University, Philadelphia calling their new technique “stereoecephalotomy.” The goal was to perform accurate ablative procedures instead of usually undertaken frontal lobotomy in behavioral disorders (Wycis and Spiegel 1947).

From this point on tremendous developments in stereotactic human atlas (Schaltenbrand and Bailey 1959), neuroimaging, stereotactic frame systems (Lars Leksell 1949; Mundinger 1977; Talairach et al. 1949) and electrical devices emerged the use for deep brain stimulation as we know it today.

Self-Identification

Science

Functional neurosurgery as a rapidly growing branch of neurosurgery regards itself a natural science aiming to enhance the knowledge about the pathophysiological aspects behind disorders of the central nervous system. The goal of deep brain stimulation is the reestablishment of physiological function by means of neuromodulation.

Extensive neuroanatomic and neurophysiological investigations and observations made in

animal models elucidated the state of knowledge about neurobehavioral, pain, and movement disorders in the last century.

The application of electrical stimulation as a therapeutic tool can be traced back to 15 AD, where Scribonius medicated gout pain. In the second century Galenos of Pergamon, Galen, applied “neuromodulative” therapy via electrical fish to treat headache and gout pain.

Going further into the eighteenth century there were several works by Christian Gottlieb Kratzenstein, a scientist, who was engaged in electricity research and its impact in the treatment of pain syndromes. In 1744, he published a monograph concerning this issue “*Abhandlung vom Nutzen der Elektrizität in der Arzneiwissenschaft*.”

In the same year, Ewald Georg von Kleist, a Prussian scientist and advocate contrived the “Kleistsche Flasche,” a condenser made electricity useful as medical treatment tool.

Hundred years later, Eduard Hitzig and Gustav Fritsch, both neuroscientists, observed motor response after stimulation of the motor cortex in a dog. In 1874, Robert Bartholow first performed motor cortex stimulation in humans.

The pivotal turning point of deep brain stimulation can be seen in the landmark development of Spiegel and Wycis human stereotactic apparatus in 1947. This reflects the hour of birth of stereotactic-guided deep brain stimulation. Many neurosurgeons, namely, Lars Leksell, Jean Talairach, Philipp L. Gildenberg, etc., visited Spiegel and Wycis in Philadelphia to design stereotactic frame systems after they have returned to their departments.

In this era, chronologically, the first indications of ablative and/or chronic subcortical stimulation were neuropsychiatric disorders followed by intractable pain syndromes and at least movement disorders. Interestingly, deep brain stimulation in behavioral disorders (obsessive-compulsive disorder (OCD), Depression, Tourette Syndrome) reemerged in the last years with preliminary auspicious results. For instance, Spiegel and Wycis started with medial thalamotomies in psychotic patients in 1947. Intraoperatively, neurophysiological patterns by

electrical stimulation means were performed prior to lesioning to confirm the intending targets.

In the coming decades until now expansive growing knowledge in neuroscience (neuroanatomy, neurophysiology, neuropathology, and neuroimaging) and clinical evaluation by prospective, randomized studies conducted deep brain stimulation to a treatment modality which is well established and evidence-based in the treatment of movement disorders and pain, furthermore with promising results in neuropsychiatric disorders.

The growing numbers of societies and scientific journals addressed to deep brain stimulation (WSSFN, ESSFN) reflects the increasing interest in this field and emphasizes the future potential of this subdivision of neurosurgery.

Characteristics

DBS differs from other disciplines in many ways. First the prospects of DBS are strongly linked with the technical development of the applied devices and, therefore, more influenced by the available surgical equipment.

In addition, the authors believe that the growing field of indications in the coming future will pose unexpected neurosurgical challenges. Well-established and newly introduced treatment modalities have to be evaluated carefully, even more in a long-term fashion. Neuroscience-based investigations contributed and will account for this relevant matter.

The main goal of functional stereotactic neurosurgery is to reestablish altered function of motor systems, pain processing, and behavior.

Due to these facts, a patient's treatment should include substantial preoperative evaluation, defined surgical procedure, and close-mesh endorsement in the postoperative course by interdisciplinary means.

Relevance to Science and Religion

As mentioned above, there has been increased interest in behavioral disorders again in the past

two decades after a silent period of nearly 30 years. Great research efforts have been undertaken to lighten the poorly understood pathophysiological background by neuroscientific means.

However, cognition, emotion, and behavior, more precisely, neuromodulation of related disorders delivered through deep brain stimulation, requires interdisciplinarity in every available fashion, and ethical issues have to be taken into account strictly.

Sources of Authority

The sources of authority of deep brain stimulation were already named in part. The authors prefer to summarize this content in a chronological manner.

Deep Brain Stimulation in Neuropsychiatric Disorders

Jose Delgado, neurophysiologist, became known for his work with chronically implanted electrodes which were connected to a subcutaneous receiver (Stimoceiver) which allowed neuromodulation by radio waves in psychotic patients. He researched the effects of neuromodulation in several animal models and humans. In 1969, he published a book titled *Physical Control of the Mind: Toward a Psychocivilized Society*. This fact may reflect the enthusiasm carried out at that time (Delgado 1965).

Carl-Wilhelm Sem-Jacobsen started in the 1950s with a series of 213 patients (123 with neurobehavioral disorders) in whom "depth electrography and depth stimulation" was performed. The main goal was to detect suitable target areas by electrophysiological recording and thereafter to generate irreversible lesions (Sem-Jacobsen 1963).

The thin ethical line of this issue became obvious regarding the contribution of Robert Heath, who was engaged in neuromodulative therapy in patients suffering from schizophrenia, pain, and epilepsy since the 1950s. During an intraoperative stimulation session in schizophrenic patients in the septal area, some patients reported "euphoric" and "pleasant" perceptions

(Baumeister 2000). An example for unethical and dubious practice was the septal area stimulation performed by Heath in 1972 in a homosexual individual aiming to induce heterosexuality behavior.

Based on neuroscientific research, profound ethical considerations and interdisciplinary collaboration DBS was inaugurated in Tourette Syndrome and obsessive-compulsive disorders (OCD) in the last decade of the last century by Vandewalle et al. in 1999 and Bart Nuttin from Leuven (Nuttin et al. 1999). This displayed a turning point and again neuropsychiatric disorders came into interest in the functional community.

Deep Brain Stimulation in Pain and Epilepsy

David Hosobuchi and Guillaume Mazars introduced in the mid-1970s the sensory thalamus and the periventricular/periaqueductal gray as proposed targets for pain relief in patients suffering from deafferentation pain (Mazars 1975; Hosobuchi et al. 1977).

Epilepsy came into focus at the end of the 1970s. Irving Cooper demonstrated a marked reduction in medical refractory seizures due to deep brain stimulation of the anterior nucleus of the thalamus (Rosenow et al. 2002). Ten years later, Velasco published another remarkable series of intractable epilepsy treated by thalamic stimulation.

Nowadays neuromodulation is an essential part of neurosurgical epilepsy treatment concepts.

Deep Brain Stimulation in Movement Disorders

Neuromodulation constitutes a well-established and evidence-based treatment modality for Parkinson's disease (PD), essential tremor (ET), and dystonia.

Neurosurgeon Alim-Louis Benabid and neurologist Pierre Pollak introduced in 1987 and 1993 high-frequency stimulation in the VIM thalamic nucleus and subthalamic nucleus as proposed targets in PD. Undoubtedly, both can be regarded as pathbreaking pioneers in neuromodulation for movement disorders (Benabid et al. 1987; Pollak et al. 1993).

Going back to the days of Spiegel et al. (1947) many neurosurgeons have contributed to this issue. In principle, the common procedure to identify subcortical brain structures suitable as targets was electrophysiological evaluation prior to lesioning.

Natalia Petrova Bechtereva (1925–2008), neurophysiologist, worked in Leningrad and developed the first concept of chronic stimulation as a therapy in the 1960s/1970s. Patients suffering from PD were treated over a time course of 1.5 years with externalized electrodes due to the lack of implantable devices at that time (Hariz et al. 2010).

German neurosurgeon Fritz Mundinger treated patients with cervical dystonia with unilateral chronic thalamic stimulation with beneficial results. Irving Cooper neuromodulated thalamic somatosensory nuclei in various movement disorder conditions. In addition, many stereotactic-guided ablative procedures (thalamotomy, pallidotomy) were performed through the 1970s/1980s. This lesioning surgery precisely the identified targets formed the fundament of later-executed reversible DBS with permanent implantable devices.

Ethical Principles

The Hippocratic Oath modified by the Helsinki declaration (1971) builds the frame for ethic-guided proceedings in neuromodulation. In our opinion further attention has to be addressed to autonomous wishes of patients, psychosocial impact, stimulation effect on patients' personality, and benefit/risk ratio.

Key Values

The key value of deep brain stimulation is to restore distortion of function by motor symptoms, pain symptoms, and neuro-behavioral means. The neuromodulative strategy is based upon substantiated knowledge including neuroanatomy, neuroimaging, and neurophysiology.

Conceptualization

The authors summarize the following issues in the way they are influenced by DBS. This holds true for some issues more than for others.

Nature/World
Human Being
Life and Death
Reality
Knowledge
Truth
Perception
Time
Consciousness
Rationality/Reason

DBS is aiming at improving distortion of motor, pain, and behavior function. Nevertheless, some beneficial effects go together with unexpected alteration related to more abstract issues like mood, behavior, perception/self-perception, and psychosocial interaction with the environment. The above mentioned points could be affected by DBS in a short- as well as in a long-term manner; for that reason, it seems advisable to take those issues into consideration by conducting a multidisciplinary treatment approach in DBS patients.

Mystery

Functional stereotactic neurosurgery and mystery contradict themselves as DBS underlies natural law. Many unexplained issues concerning DBS remain still “mystic” until neuroscience-based investigations highlight our background knowledge.

Relevant Themes

A critical issue in DBS as regards “Science and Religion” is the fact that beneficial results can be associated with non-beneficial effects concerning mood, cognition, behavior, self-perception, and perception of the environment. Thus, careful selection, long-term mentoring, and psychosocial assistance are required to intercept or ameliorate occurring difficulties, especially in younger patients.

Description

On the website of the World Union of Deists we find the following definition of deism: “Deism is the recognition of a universal creative force greater than that demonstrated by mankind, supported by personal observation of laws and designs in nature and the universe, perpetuated and validated by the innate ability of human reason coupled with the rejection of claims made by individuals and organised religions of having received special divine revelation.”

According to this, deism is characterized by four elements: (1) recognition of a universal creative force greater than mankind; (2) centrality of the observation of laws and designs in nature as a basis for belief; (3) fundamental trust in the ability of human reason to know God; and (4) rejection of all claims of special divine revelation. One might ask if all four elements were also essential for classic deism, that is, as it was understood toward the end of the seventeenth and during most of the eighteenth century. Furthermore, what happens with one of the ideas that a great many associate with deism, namely, that which states that God created the universe at the beginning and allowed it to run onward according to laws of nature without ever intervening with its functioning?

The term *deism* was probably first used by Calvinist Pierre Viret (*Instruction chrestienne*, 1564), who applied it with a negative valence to a group of Lyonnaise anti-Trinitarians. Later, in the second half of the seventeenth century, it was appropriated as a self-characterization by those who wanted neither to be atheists nor uncritically accept the tenets of revealed religions, concretely Christianity. For them, human reason was the most adequate way to know God. Thus, natural or rational religion became the criterion to judge revelation. At first *deism* and *theism* were almost synonyms, but soon began to diverge. Almost a century later Diderot (*Ouvres*, ed. by J. Assézat, I, 13, 479) tried to differentiate between them saying the deist denies the possibility of special divine revelation altogether, while the theist allows for it. This is also the way we tend to see it today: the difference between *theologia rationalis* and *theologia revelata* marks in part the divide between deism and theism.

The cradle of deism was England, where it was anticipated by Lord Herbert de Cherbury in *De veritate* (1619; many of the texts mentioned in this paragraph and the following one can be found in Gay 1981). Locke and Newton's ideas paved the way for it. Its most important advocates in the island were John Toland (*Christianity not Myste-rious*, 1696), Samuel Clarke (*A Discourse concerning the Being and Attributes of God, the*

Obligations of Natural Religion, and the Truth and Certainty of the Christian Revelation, 1705–1706), Anthony Collins (*A Discourse of Freethinking*, 1713), and Matthew Tindal (*Christianity as Old as Creation*, 1730). Deism arose in response to the deep transformation European society and culture underwent in the seventeenth century. This transformation had three main vectors: discovery of cultural diversity, which undermined the uniqueness of Christianity; religious conflicts, especially the Thirty Years' War and English Civil War, which fostered the search for natural religious truths that could be universally accepted; and advances in scientific knowledge, which established the laws of nature that the now unified universe strictly obeys in its functioning. This new trust in human reason and its autonomy was extended to the realms of both religion and morality.

Deism then irradiated from England to France, Germany, and North America. In France, it became popular among the first enlightened philosophers, many of whom converted to atheism. In spite of calling himself a theist, the most conspicuous French deist was Voltaire (*Candide ou l'optimiste*, 1759). Also Jean-Jacques Rousseau ("Profession de foi du vicaire savoyard," *Emilio*, Book IV, 1762) is usually considered a deist, although for him religion had more to do with emotions than reason. Deistic ideas also pervaded the German Enlightenment. Leibniz and Wolff played a significant role in their extension, although they formulated them in the frame of a systematic philosophy; the German deist par excellence was Hermann Samuel Reimarus (*Apologie oder Schutzschrift für die vernünftigen Verehrer Gottes*, 1774–1777). The North American "founding fathers" were also profoundly influenced by deism. Its most fervent advocates were Thomas Paine (*The Age of Reason*, 1794) and Elihu Palmer (*Principles of Nature*, 1801).

There was a wide variety of opinions among deists concerning all main points. For example, natural religion and revealed religion were differently related to each other depending on the understanding of the relationship between faith

and reason. Some deists tried to harmonize them and held that Christianity, once expurgated from superstition, was the true natural religion ("constructive deism"); others saw faith and reason as incompatible, championing the replacement of Christianity for natural religion ("critical deism," "decadent deism"). All denied, however, the possibility of miracles and other supernatural events. That must be seen as a consequence of an immanent concept of reason. Still, reason itself was differently understood, ranging from rationalist reason, of a systematic and deductive kind, to enlightened reason, which was above all the abilities to analyze empirical reality. If Herbert of Cherbury still relied on the innate ideas placed in the human mind, the post-Lockean deists gave an increasing relevance to the observation and study of nature as a way to the knowledge of God, at least of His existence. In this context, the development of modern science, especially of mechanics, was of paramount importance (see Gestrich 1981).

The scientific advances of the age gave rise to the *machina mundi* image, that is, the world as a closed, law-determined causal nexus which runs "automatically" obeying such in-built laws and does not need intervention from outside. This seemed to ask for a corresponding image of God as the Supreme Architect or Engineer who creates the world at the beginning and lets it run alone from then on, a sort of Aristotelian God. Such a reduction of divine action to the act of initial creation, even when detached from the *machina mundi* image, is what we usually associate with deism. But neither English nor German deists subscribed to it; on the contrary, their doctrines were a reaction against a world without God, either in the form of a rational pan(en)theism (in England) or through the identification of the *gubernatio divina* with the global act of creation and conservation of the world (Leibniz and Wolff). The popularity of the argument from design or teleological argument must be understood as a consequence of this frame of mind too (see Gawlick 1972). The one author who most clearly denied divine providence and advanced a wholly nonreligious view of history

and human destiny was Voltaire. The pervasive existence of evil in the world was his main stumbling block.

The decline of deism, already started, was almost inevitable once Hume and Kant's ideas were widely received, even though both of them had some affinity with deistic thought. Hume refuted the alleged chronological priority of ethical monotheism over polytheistic cult religion, questioning the validity of natural religion. Kant clipped the speculative wings of reason and showed the impossibility of any rational theology which claims to be theoretically certain knowledge, undermining the teleological argument as well as any other argument for the existence of God (see Byrne 1993). In the last decades, we assist, however, to a revival of deism, above all in the United States. It takes different forms, for example, humanistic, scientific, Christian, spiritual deism, pandeism, and panendeism. In general, it is more modest regarding the ability of reason to define God's attributes and the precise character of his relationship with the world. (That is why it opts for certain vagueness when speaking of God, as it is obvious in our opening quotation.) But lacking a serious confrontation with Kant's objections it still holds to the centrality of the argument from design, as the controversial "conversion" to deism of the notorious atheist Anthony Flew in 2004 clearly shows. Other characteristics of modern deism are its marked critical stance toward revealed religion and the high moral standards it pursues.

As an abstract model of God's relationship with the world, deism plays a secondary but important role in present mainline Christian debates about divine action. In an ideal typology, deism is one of the two conceptual positions against which theism has to be defined as a middle way, the other being either pantheism or occasionalism. In both cases, deism stands for extreme creatural autonomy, while pantheism or occasionalism signals extreme dependence on God. Furthermore, deism is used sometimes against the Anglican theologian Maurice Wiles, who does not allow for special divine actions, as

a stylized reproach for not giving enough room to divine providence (see Struch 1990). However, what he really does is to subsume particular providence within general providence, while affirming continuous creation. In other occasions, as in the debate over the physicist Paul Davies' proposals, deism is used almost as a synonym of natural theology.

Deism exerted significant influence in the configuration of Western modern culture. And such influence can be still perceived today in the requirement of universality in the concept of God, as well as in the not uncontroversial pursuance of coherence between both religion and reason and religion and morality (see Byrne 1989).

Dementia

Katharina Fink and Rainer Hellweg
Klinik für Psychiatrie und Psychotherapie,
Charité - Universitätsmedizin Berlin, Campus
Charité Mitte (CC15), Berlin, Germany

Description

Dementia is a clinical syndrome often caused by chronically progressive diseases of the brain that are combined with an impairment of higher cortical functions, including memory, orientation, speech, ability to talk, ability to reason, and decision making. The cognitive disturbances in dementia are often accompanied by changes of social behavior, motivation, and emotional control but no disturbance of consciousness is observed. Dementia can have a diverse picture, can be studied separately or as part of other diseases, like Parkinson's disease or multiple sclerosis, and can be rapidly progressing, as in Creutzfeldt-Jakob's disease, or slowly progressing, as in Alzheimer's disease.

Dementia science is providing research into the cause, cure, care, and prevention of dementia. It has grown in importance as populations in the Western world and elsewhere are aging and aging is the most important risk factor for dementing diseases.

According to the clinical picture, the syndrome can be attributed to different etiologies, but a definitive diagnosis of the disease can as of today only be made postmortem. The classification of non-Alzheimer conditions is undergoing major changes, moving away from syndromic toward molecular and gene-based approaches.

Dementia science is dealing with the fundamental problem that aging on its own is not a disease. In the longitudinal and prospective Minnesota nun study, nuns with the same environmental surrounding were followed with neuropsychological testing over several years and their brains were assessed by a pathologist showing that even in individuals with high cognitive

functioning shortly before their deaths multiple pathological senile plaques were present (www.healthstudies.imn.edu/nunstudy). In different statement papers, the categorization of, e.g., Alzheimer's dementia is discussed. Due to the improvement of technologies in imaging, laboratories and neuropathology preclinical "in vivo" stages of dementia can be identified leading to the question where to draw the line and whom to treat. So far the WHO definition of diseases is still relevant: A "disease" including dementia is inextricably associated with signs of malfunction and suffering.

Self-identification

Science

Dementia science has grown out of the need to investigate the cause of this syndrome and to eventually cure and prevent this clinical picture as dementia occurs frequently in an aging population, causing a burden to the patient itself by losing their independence and primary personality, but also to caregivers and leading to social costs exceeding the costs of health insurance expenditures almost by a factor of five in mild and moderate disease stages (Schwarzkopf 2011).

Characteristics

Dementia science relates to adjoining specialties like geriatrics, neurology, and psychiatry. However, dementia science is distinctive to geriatric medicine because it attempts to shed light on the underlying pathology of conditions that go beyond conditions of normal aging, even though some dementias' risks rise with increased age. Dementia science uses the knowledge that neurology offers about the relationship between clinical pictures of deficits and the topography of lesion location within the nervous system. It distances itself from neurology by focusing only on neurodegenerative diseases; included dementia syndromes in neurological conditions like multiple sclerosis or Parkinson's

disease at the same time. Patients with dementia are often treated as psychiatric patients due to their deficiencies in higher cortical functions resulting in changes of social behavior; care of demented patient is therefore often multidisciplinary.

Relevance to Science and Religion

This scholarly area is not the prime object of the research field mentioned as too little is still known about the diseases themselves. But religiosity, faith, and spirituality have been found to be protective, aiding well-being for both patients with dementia and their caregivers.

Sources of Authority

The early authorities in dementia science used to be neuropsychiatrists who were dedicated clinicians with a passionate interest in neuropathology, bridging the gap between brain, in particular the cerebral cortex, and behavior. A first good description of dementia was given by Philippe Pinel (1745–1826) in the late eighteenth century (Torack 1983). Around this time, dementia was mentioned in the *Encyclopédie Française*. Alzheimer (1864–1915) when describing Auguste D. at a conference in his lecture called “About a remarkable illness of the cerebral cortex” in 1906 set a starting point for the research in a new entity of patients with an early onset of behavioral changes later named after the describer himself as “Alzheimer’s disease.” Around this time, the Prague group led by Pick and the Munich group around Kraepelin with Lewy, Alzheimer and Nissl, described several different conditions with dementia, being name giving to several neurodegenerative conditions, like Lewy-body dementia and Pick’s disease.

As shown in the “Minnesota nun study” the “dual clinicopathological concept” of the Alzheimer’s disease might lead to confusion, as patients with “senile” plaques might not present with behavioral changes, not qualifying for the diagnosis from a clinical point of view, new

concepts were described lately by Bruno Dubois from the Salpêtrière hospital in his article “Revising the definition of Alzheimer’s disease: a new lexicon” (Dubois et al. 2010).

The “European Alzheimer’s disease consortium” is a network of over 50 European centers working with Alzheimer’s disease and related dementias, setting up large interventional studies for understanding, prevention, treatment, and management of the disease or its complications.

Ethical Principles

As in all medical disciplines, dementia science is guided by the oath of Hippocrates. For medical research, the Declaration of Helsinki from 1971, provides the ethical principles for human research.

Key Values

The key values of dementia science are to maintain the patient’s dignity and to alleviate suffering resulting from neurodegenerative diseases affecting cortical functions. Dementia science is trying to establish algorithms for prevention of dementia syndromes, supporting curative attempts and therapy options delaying the worsening of dementias (cf. Hellweg et al. 2012).

Conceptualization

Nature/World

Nature is conceptualized as the biotic and abiotic world and spans from the subatomic to the cosmic in scale. In particular it refers to phenomena not created by humans, as an antonym to culture. The world comprises the material and the interspersed space of the universe.

Human Being

The human being is considered as a biological being equipped with a highly developed complex brain, which enables unique functions including speech, abstract thinking, creativity, and the

development of ethical categories such as morality, science, and art. Thus, humans are considered to be distinctive from the rest of the animal world in virtue of the unique capacities of the human brain.

Life and Death

Life is conceptualized as the presence of physical functions in biological systems ranging from bacteria over plants and animals to humans. In the human body, it includes functioning of the different organs, including the *nervous system*. Death is considered the cessation of such physical functions. A special case, which has raised ethical challenges for medicine is that of so-called “*brain death*,” which is observed in intensive care medicine. Here, non-brain bodily functions are maintained, but there is no evident brain activity.

Reality

Reality is considered the physical world around us which humans can observe with their senses.

Knowledge

Knowledge is the understanding of a subject. This understanding should be based on adjusted true belief. It can be preserved in the cognitive system and can be put into contexts. Disturbances of higher cortical functions like in dementia can inhibit acquisition and retention of knowledge.

Truth

Truth is conceptualized as the supreme reality underlying facts and rules. Accordingly, truth is assumed to be absolute or universal which humans can grasp only partially.

Perception

Perception is the conscious sensation of the forces and influences the external physical world exerts on living beings. Diseases of the human brain may disrupt or impair perception.

Time

Time is the fundamental category of ongoing change in the world. Humans can measure time

objectively and perceive it owing to the changes observed in the surrounding environment.

Consciousness

Consciousness is the responsiveness of subjects to any physical stimulus in the outside world. It can be graded in different levels of alertness ranging from drowsiness to full alertness, which comprises crystal clear orientation concerning location, time, situation, personal biography, and full mental capability. Diseases can impair consciousness globally.

Rationality/Reason

Rationality is a foundation of accountable and responsible human behavior and of understanding reason as ultimate authority. It is impaired in mental diseases such as dementia or neuropsychological *disorders*.

Mystery

Mystery is often considered to be contradictory to modern medicine, including dementia science. However, modern medicine in principle acknowledges a place for mystery – i.e., that which is yet unknown, and thus, grants that contemporary knowledge may not have elucidated the entire physiology of human kind. In this view, mystery is understood as potentially explainable after accumulation of adequate scientific knowledge.

Relevant Themes

As in all other medical specialties, a critical issue in dementia science as regards to “Science and Religion” is the notion of subjectivity. As discussed in many statement papers, it is not predictable which individual will develop dementia with a certain outcome. So far dementia research is done on a group statistical level, not being adapted to each individual.

Deontology

Joakim Sandberg

Dept of Philosophy, Linguistics & Theory of Science, University of Gothenburg, Gothenburg, Sweden

Related Terms

[Deontological](#); [Deontological ethics](#); [Ethics of duty](#); [Non-consequentialism](#); [Rule-based ethics](#)

Description

Deontology or deontological ethics (the terms stem from the Greek root *deon* meaning “obligation” or “duty”) is an approach to ethics which judges the morality of actions based on their adherence to a set of (most often strict) action-principles or rules. These rules typically divide actions into three moral categories: (1) those that are obligatory (prescribed, required), (2) those that are prohibited (forbidden, illicit), and (3) those that are permissible (neither obligatory nor prohibited). Deontological ethics is commonly contrasted with teleological or consequentialist ethics (e.g., utilitarianism) which holds that the morality of actions is determined by their consequences. Accordingly, deontological ethics holds that it may be our duty to refrain from performing certain actions (like killing and stealing) irrespective of what the consequences of doing so will be – it is, for instance, typically

morally prohibited to actively and deliberately kill someone even when this is the only way to save several others. Likewise it may be our duty to perform certain positive actions (like defending ourselves or helping others) irrespective of circumstance and situation.

A fairly straightforward example of deontological ethics may be the Biblical appeal to the “Ten Commandments” or *Decalogue* as the ultimate moral code. These commandments (“thou shalt not kill,” “thou shalt not steal,” etc.) have historically been understood as strict moral commands and prohibitions which require constant obedience, and similar moral codes can be found in almost all religious traditions. Many deontological codes indeed have religious roots, but it may be noted that the connection to religion is not necessary. A secular example of a deontological code could thus be the United Nations’ Universal Declaration of Human Rights, which may be taken to specify a list of humanistic duties and prohibitions. Of course moral positions need not involve complete catalogs of duties and restrictions in order to be deontological and, consequently, many participants in contemporary ethical debates may be said to hold (nondescript) deontological views. Typical examples may be when debaters claim, for instance, that abortion always is morally wrong, or that euthanasia should be strictly forbidden.

Deontology is probably better seen as general approach to ethics, or as a group (or sort) of moral positions (or codes, theories, traditions), than as a uniform moral position as such. Numerous variations of the appeal to moral action-principles exist, namely, and with widely different characteristics as well. A first dimension of variation is what more precise set of principles that is thought to apply, i.e., exactly what actions are listed as duties or contrary to duty. While the Biblical commandments include a duty to honor one’s parents and the One True God, for instance, it may be noted that the Universal Declaration of Human Rights makes no mention of either – and, conversely, the Declaration suggests that discrimination on the basis of race, color, and sex is contrary to duty, which the Decalogue makes no mention of. Many contemporary ethical

debates are indeed debates between directly opposing deontological camps: whereas some argue that abortion is strictly forbidden, for instance, others stress the absolute right of women to choose. Both of these positions may be deontological in the sense of being appeals to action-principles rather than consequences. Thus while most deontological codes contain a prohibition against the active and deliberate killing of adult human beings, perhaps, many other duties are widely contested.

Different deontological positions may also vary in how stringent these duties are thought to be, i.e., to what extent the rules allow for exceptions for countervailing moral reasons. In the strictest kind of view all duties are absolute, i.e., there are no circumstances or situations in which one is morally allowed to perform a prohibited action or to refrain from performing one’s positive duties. This is sometimes called moral absolutism. However, for reasons discussed below, some proponents of deontology argue that there only can be *prima facie* duties, i.e., duties which under certain (but perhaps only exceptional) circumstances can be overridden by opposing moral considerations. In this way one may suggest, e.g., that it is contrary to duty to steal in normal cases – and therefore also *typically* morally wrong – but that one should not abide by this rule (and so it is not wrong) should, say, the continuation of the entire human species depend on this particular instance of stealing. This view is deontological but not absolutist.

Philosophers and theologians keen on deontological ethics – commonly called deontologists – have long argued that this sort of ethical perspective has a range of characteristics which should make it more appealing than rival ethical theories (e.g., utilitarianism and virtue ethics). Firstly, deontological ethics would seem to fit well with public conceptions of both the structure and point of morality in general. Most people (or at least so it is argued) rather straightforwardly associate morality with as a set of more or less strict rules designed to keep everyone in check and to in this way facilitate social interaction. Indeed the fact that so many religious traditions include deontological considerations

may be taken as an indication of this kind of public support – and perhaps, some suggest, society simply could not work without some kind of deontological moral framework.

Secondly, deontological ethics is often suggested to flow directly from what philosophers call the universal nature of morality. Reflecting on the nature of morality as such, many agree that one of its most basic or essential features seems to be that it goes beyond bias and prejudice and, thus, that it treats everyone the same in some important respect. But from this feature, it is often argued, it would seem that moral rules as such cannot treat separate persons, situations, and circumstances differently but must be more general in exactly the way that deontological principles are. Morality must simply consist in rules that apply to everyone in the same way.

A third and related argument for deontological ethics is that strict action-principles sometimes are thought to be the only way of avoiding so-called slippery slopes in moral thinking. The case of abortion may once again be illustrative here: as soon as one kind of exception is allowed (e.g., for conception by rape) it may seem arbitrary not to allow others (e.g., for pregnancies unwanted for other reasons) and so on and so forth, until one ends up in an unexpected and unwanted moral position (in this case, roughly, that “anything goes”). In this way, it is argued, deontology may be the only cure against an “anything goes” attitude either in society in general or (at least) in ethics in particular. Once again society would be worse off without deontological moral principles.

Not everyone agrees with these arguments, and it should be noted that they all are debatable. The universality of morality can probably be understood in many ways, for instance, and it need perhaps not be taken to imply that ethical principles cannot be sensitive to circumstances. Furthermore, many philosophers have been critical of the kind of loose slippery slope arguments outlined above, since there is the obvious possibility of being able to carve out some plausible middle ground – that is, of having good reasons for allowing a limited set of exceptions while disallowing others. Philosophers and theologians

more keen on rival ethical theories have long argued that deontological ethical thinking not only lacks fundamental justification but, what is more, also has a number of serious drawbacks and problems. And we may say a bit more about these counterarguments here since this discussion is highly illustrative of both deontology and its rivals.

A first problem concerns the kind of moral agents envisioned by deontologists. The writer most commonly associated with deontological ethics is the German philosopher Immanuel Kant, and Kant famously suggests that duty must be done for the sake of duty alone. That is, Kant argues that one should perform one’s obligations only and exactly because they are one’s moral duties – and not, for instance, because one happens to find killing repulsive, or because one happens to like telling the truth. But many critics (especially from the virtue ethics camp) find this idea inherently problematic. Kantian deontologists, they suggest, to some extent seem to hail a form of heartless rule-followers that are far from our ideal of the virtuous person. Suppose, for instance, that your friend comes to visit you in the hospital but, when you ask her why she does this, she simply replies “because I believe it is my moral duty to come.” Few people would probably be impressed by such a reply, and this friend – although she perhaps performs the right actions – seems to lack a further important part of what morality should teach us to have; namely, emotions stemming from virtuous character traits. While deontological ethics may be right about the morality of individual actions, then, the first criticism is that it may be wrong about the morality of character.

Is this criticism correct? In defense of deontology, it should perhaps be said that not all deontologists need agree with the Kantian view above. Indeed it may be noted that Christian ethics puts a lot of emphasis on emotion and virtue, while still reserving a central place for the Decalogue’s strict commandments. Thus it seems entirely possible for deontologists to agree with the critics in that emotion and virtue also are important parts of morality. But, then again, perhaps this is simply adding things to

deontological ethics which was not there in the first place. According to critics, in any case, there is a fundamental discrepancy between deontology's appeal to rigid rules and our folk conception of a virtuous person.

A second and related problem concerns the rigidity of deontological rules as such, and this may be formulated either as a problem internal to deontological thinking or as an external criticism of such thinking. The internal problem is brought out by considering cases of conflicting duties: say, for instance, that I make a promise to you that I will kill your mother. If both killing people and not fulfilling one's promises are strictly forbidden (i.e., always morally wrong) then it would seem that I cannot avoid acting wrongly in this situation, since both killing and not killing your mother are morally prohibited action-alternatives. What is more, it would actually seem that deontological ethics ceases to give me guidance on what to do here, since no action-alternative is held out to be better than the other. These are strange results since we naturally turn to ethics for action-guidance exactly in difficult cases, and most people would probably say that not killing your mother should be my obvious choice. The external criticism is basically a generalization of this last point: it is noted (especially from the utilitarian camp) that there are many situations where deontological rules just seem too rigid, and where we intuitively allow for exceptions. Perhaps killing one to save two is morally wrong, but what about killing 1 to save 20 – or two million? Few individuals, when consulting their own ethical intuitions, would be ready to accept moral rules as rigid as deontological ethics sometimes makes them. And therefore deontology has been accused of not only fostering *heartless rule-following*, but indeed *pointless rule-worshipping*.

As noted above, some deontologists try to avoid these problems by adjusting the stringency of (some) duties or rules. Thus it is often suggested, for instance, that the prohibition against killing is more stringent than the prohibition against breaking one's promises (although some deontologists actually have it the other way around). Furthermore, it is sometimes conceded that there may be exceptional cases where

the rules are overridden by countervailing moral considerations; for example, when the lives of great many people are at stake, or when one is in a practical dilemma of the kind noted above. Such theoretical moves may provide an easy way out of the particular problems noted above, but it should of course be noted that deontologists here risk the same kind of slippery slope problems as their rivals. That is, once one exception is allowed, what about others?

A third problem is perhaps more technical and concerns the internal structure of deontological rules. The deontological prohibition against killing (or murder), for instance, is of course typically taken to forbid me from actively and deliberately killing someone – e.g., from shooting someone on the street just for fun. However it may be noted that it is not normally taken to castigate my passively allowing someone's death; e.g., when I see someone else aiming his or her gun but I refrain from interfering. Nor am I acting wrongly when my behavior inadvertently leads to someone's death; e.g., when I happen to shoot someone while aiming for a tree or something similar (given, of course, that I have not been inappropriately inattentive). This sort of thinking obviously relies on two crucial kinds of distinctions: (1) that between actions and omissions (or active and passive actions) and (2) that between deliberate and nondeliberate behavior (or intended and merely foreseen outcomes). But can these distinctions really be upheld? Many philosophers have criticized similar distinctions for being both theoretically and normatively untenable, and this is sometimes done with reference to (variations of) the following kind of thought experiment.

Say that you are standing next to a railroad track when you suddenly see a runaway trolley heading straight toward five innocent people. The only way for you to stop the trolley would be to throw a switch which you happen to stand next to; an action which would cause the trolley to roll down a side track. Unfortunately, there is one person on that track as well and your throwing the switch would directly kill this person. What should you do? Empirical studies confirm that, when confronted with this kind of case, most

people say that you should throw the switch. But this runs directly against what seems to be a cornerstone of deontological ethics, namely, that actively killing someone should be worse than passively letting someone die – note that you are actively killing the one if you throw the switch, whereas you only would be letting the five die if you did nothing. Deontologists may of course insist that the public intuition to this case is wrong, but as noted above they often wish to appeal to public conceptions of morality in support of their views.

Some deontological camps have tried to revise their position in light of this kind of problem. According to an official Catholic dogma known as the Doctrine of Double Effect, for instance, actions with both good and bad effects (like the one above) may be morally permissible as long as (1) the good clearly outweighs the bad and (2) the good effects are not brought about *directly through* the bad effects (this is a rough simplification of the Doctrine). On this view, it may indeed be permissible to throw the switch in the case above, one may note, since it, firstly, leads to one instead of five dying which clearly is good, and, secondly, the bad effect (the death of the one) is only an unfortunate side effect of the good (that five lives are saved). However, it would not be permissible on this view to, say, directly push a heavy guy in front of the trolley to make it stop and *in this way* save the five. Even though this action has the same outcome, namely, the bad effect is no longer an unfortunate side effect but actually a necessary component in what brings about the good effect. Now, is this Doctrine theoretically plausible? Once again one may note the obvious risk of watering down the heart of deontological thinking by adding these exception clauses. According to critics, furthermore, the kind of distinctions that deontologists will have to conjure up in order to explain our reactions to further variations in these cases (indeed many further variations have been discussed!) simply seem too arbitrary or ad hoc to be plausible.

A fourth and final problem for deontological ethics concerns the ultimate justification of any given deontological code. Even if one accepts

that deontological ethical thinking can be attractive as such, there is still the question of exactly why one should accept this or that more specific set of deontological rules. For instance, why should killing and stealing be on the list of prohibitions and not, say, frowning or picking one's nose? A possible answer open to deontologists, as our discussion above indicates, is that this all boils down to judgments we intuitively – or perhaps *naturally* – make: Most people simply intuitively judge that certain actions are morally prohibited, or “feel” that others are permissible. Another possible answer, open especially to religious deontologists, is that the deontological code ultimately comes from divine commands, unveiled in scripture or some other way. This is sometimes called the Divine Command Theory; that is, that moral justification ultimately must come from God or, more specifically, that certain actions are morally prohibited simply because God says so. The Divine Command Theory was immensely popular among theologians and philosophers during Medieval times.

Many modern critics, however, have been largely unimpressed by both of the answers outlined above. And so have some deontological philosophers. The bulk of Kant's moral philosophy, for instance, is basically an attempt of providing deontological ethics with a more robust fundamental justification. And Kant is generally taken to suggest two more sophisticated ideas of what could justify a given deontological code: First of all, Kant argues, most examples of deontological duties can be justified by an appeal to the universality of morality again. Since morality must consist in rules that apply to everyone in the same way, he contends, it is immoral to perform actions which one cannot at the same time will that everyone performed. But this directly implies, for instance, that it is wrong to lie. It is, namely, impossible to lie while at the same time willing that everyone lied; because in a world where everyone lied no one would expect anyone to tell the truth – and so it would be impossible to lie. And the same goes for most of the other items on the deontological list, Kant argues.

A second suggestion from Kant is that many deontological duties can be justified from

appealing to the core value of dignity (or respect). If morality requires that we treat everyone the same in some important respect, then we cannot treat others merely as means for our own ends, but we must treat them as ends in themselves. From this follows directly that we cannot lie, kill or steal, for instance, because we would then be using others merely as means for our own ends. In both of these suggestions, Kant may be said to invoke a kind of reasoning similar to the “Golden Rule” appealed to by many religions – that is, roughly the saying that “you must only treat others in a way in which you would like to be treated yourself.”

While Kant’s suggestions in the present context probably are the most sophisticated to date, it may be noted that they are both problematic. For instance, the “contradiction in the will” test may work great in the case of lying, but many suggest that it does not work in many other cases. Furthermore, many alternative interpretations exist for both the appeal to respect and the Golden Rule as such. Proponents of utilitarianism, for instance, have argued that the Golden Rule – if properly understood – actually favors their ethical perspective. Finally, there is a notable discord between Kant’s two suggestions, and some even suggest that they imply different sets of deontological rules. Perhaps Kant actually could be said to have paved the way for both of the deontological camps common on the issue of abortion (noted above): those who argue that abortion is strictly forbidden, namely, generally appeal to Kant’s first idea about the universality of rules, and those in favor of the absolute right of women to choose generally appeal to Kant’s second idea about respecting people as ends in themselves.

Exactly how deontological ethics should be justified, and what more specific moral rules it entails, are likely to be issues for much further debate.

Dependent Arising

Bhikkhu Anālayo

Center for Buddhist Studies, University of Hamburg, Hamburg, Germany

Related Terms

[Paticca samuppāda](#) (Pāli); [Pratītya samutpāda](#) (Sanskrit)

Description

The doctrine of dependent arising presents the Buddhist perspective on the nature of causality, whose understanding is considered equivalent to an understanding of the teaching of the Buddha, the Dharma (Trenckner and Chalmers 1888–1896, I 190). The centrality of this doctrine is a recurrent theme in various passages.

Thus, dawning insight into dependent arising is on record as part of a pre-awakening investigation of the nature of reality undertaken by the

Buddha (Feer 1884–1898, II 10). Complete insight into the same principle – from the perspective of dependent arising as well as dependent cessation – would have come to its completion with his attainment of full awakening. The texts then report that the Buddha reviewed this doctrine right after his successful gaining of awakening (Steinthal 1885, 1ff), further underlining its importance.

A stanza that succinctly presents the Buddha's teaching in terms of dependent arising and cessation – the mere hearing of which, according to the traditional account, led the two chief disciples of the Buddha to attaining the first level of awakening (Oldenberg 1879–1882, I 40) – has ever since been a popular theme of inscriptions.

The particular soteriological orientation of the Buddhist teachings finds its reflection in the fact that dependent arising is concerned with the factors that lead to the arising of *dukkha*, a term whose meaning ranges from barely noticeable dissatisfaction to outright suffering as inherent features of human existence (► [Dukkha](#)). Descriptions of the dependent arising of *dukkha* often take the form of a 12-link presentation. These 12 links are:

1. Ignorance
2. Volitional reactions
3. Consciousness
4. Name and form
5. Six senses
6. Contact
7. Feeling
8. Craving
9. Clinging
10. Becoming
11. Birth
12. Old age and death

The cessation of *dukkha* comes about through the cessation of the previous links in the series of dependent arising. Thus, with the cessation of ignorance, a reversal of dependent arising by way of dependent cessation takes place.

These two aspects of the Buddhist conception of conditionality – dependent arising and dependent cessation – are an integral part of another key doctrine of Buddhism, namely, the four noble truths (► [Truths, Four Noble](#)). The second of

these four noble truths is concerned precisely with the arising of *dukkha*, while the third noble truth takes up the cessation of *dukkha* or Nirvāṇa.

Traditional exegesis understands the 12-link exposition of dependent arising as extending over three consecutive lifetimes (Taylor 1905–1907, I 52). Here, ignorance (1) and volitional reactions (2) pertain to the past. The series of links beginning with consciousness (3) up to becoming (10) represent the present, while birth (11) as well as old age and death (12) are assigned to a future rebirth.

Ignorance, as the beginning point of this series, is described as being itself without a discernable beginning, since no point in the past can be discerned before which living beings were free from ignorance (Morris and Hardy 1885–1900, V 113).

Volitional reactions, the second link in the series, can be generated by way of body, speech, or mind. Such volitional reactions are held to lead in turn to a type of rebirth whose nature corresponds to their wholesome or unwholesome nature (Trenckner and Chalmers 1888–1896, I 389).

The third link of consciousness is what descends into the mother's womb (Carpenter and Rhys Davids 1890–1911, II 63). However, it is not the same consciousness that is reborn (Trenckner and Chalmers 1888–1896, I 256). Instead, according to early Buddhist thought rebirth takes place by way of the flux of consciousness, a changing process devoid of an abiding permanent entity (► [Consciousness](#)).

The remaining links then depict aspects of present life experience leading up to the arising of craving (8) as a reaction to the experience of feeling (7). This in turn arouses clinging (9) and then leads on to becoming (10), all of which are responsible for rebirth (11) and thereby inevitably for having to face once again old age and death (12).

Besides the three-life interpretation of dependent arising, the early Abhidharma tradition presents an alternative mode of interpretation, according to which the 12 links can be applied to a single mind moment (Rhys Davids 1904, 144). In this context, the link of birth (11) refers just to the arising of mental states. In other words,

according to this mode of presentation, the operation of all 12 links could take place in the present, within a single moment.

According to modern scholarship, the formulation of dependent arising by way of 12 links appears to involve a criticism of a Vedic creation myth (Jurewicz 2000). Instead of leading up to the creation of the world, the point made by the Buddhist reinterpretation of this myth would then be to reveal the conditioned genesis of *dukkha*.

The chief principle underlying this aspect of early Buddhist doctrine is the notion of specific conditionality. This principle finds its succinct expression in the dictum “when this is, that comes to be; with the arising of this, that arises.” Conversely, “when this is not, that does not come to be; with the cessation of this, that ceases” (e.g., Trenckner and Chalmers 1888–1896, I 262). In other words, specific conditions are responsible for whatever happens. Removing these specific conditions is therefore the way to prevent the same from happening again.

This principle of specific conditionality operates in relation to each of the 12 links, independent of whether the entire set is understood to refer to the present moment or to extend over three lifetimes. Illustrations of the same principle in the early discourses at times take the form of shorter listings, which may involve only five, nine, or ten links. Such variant listings confirm that the 12-link presentation is best considered a particularly prominent exemplification of the basic principle of specific conditionality.

In Buddhist thought, this basic principle extends over all aspects of existence. Nirvāṇa, however, is held to stand apart as being unconditioned and therewith the release from all that is conditioned.

Depression

Joachim Cordes

LVR Klinikum Düsseldorf, Düsseldorf, Germany

Description

According to the World Health Organization (WHO) depression is a “common mental disorder characterized by depressed mood, loss of interest or pleasure, feelings of guilt or low self-worth, disturbed sleep or appetite, low energy and poor concentration” (www.who.int). Such symptoms can become chronic or recurrent and result in an individual no longer being able to take care of his or her everyday responsibilities.

Depression can lead to suicide and results in the loss of approximately 850,000 lives every year (www.who.int). In primary care depression can be reliably diagnosed. “Antidepressant medications and structured forms of psychotherapy are effective for 60–80% of those affected and can be delivered in primary care” (www.who.int, Nice 2009). Fewer than 25% of those suffering from depression receive such treatments. There are many barriers which hinder the effectiveness of care, including a lack of resources, a lack of trained professionals and the social stigma attached to depression (www.who.int).

Intermediate phenotypes may be the link between genotype and phenotype by increasing the precision of psychiatric phenotypes and providing further insight into the underlying biology (Scharinger et al. 2011). A recent literature review of neuroimaging intermediate phenotypes of MDD and their relation to genetic risk variants shows evidence of the influence of serotonergic genes on neural intermediate phenotypes (Scharinger et al. 2011).

Comorbidity

Shared biological vulnerabilities may exist in the comorbidity of type 1 diabetes and MDD (Korczak et al. 2011). A growing body of research suggests that the prevalence of MDD in children and adolescents with type 1 diabetes mellitus is much higher than that in youth without type 1 diabetes and is linked to heightened illness severity, which suggests evidence of plausible common mechanisms (Korczak et al. 2011).

Treatment

Repetitive transcranial magnetic stimulation (rTMS) is a new treatment within psychiatry (see chapter ► [Transcranial Magnetic Stimulation](#)). The majority of trials carried out have evaluated the efficacy of high-frequency rTMS applied to the left dorsolateral prefrontal cortex (Fitzgerald and Daskalakis 2011). This “standard” form of rTMS appears to have antidepressant efficacy and its effects have now been

demonstrated in several clinical trials and a number of meta-analyses (Fitzgerald and Daskalakis 2011).

Self-Identification

Science

Psychiatry is the discipline and the clinical and scientific issues of depression involve subdisciplines of psychiatry such as psychotherapy, psychopathology, psychopharmacology and subdisciplines of research such as genetic, epidemiologic, neuroendocrine, electrophysiologic, neuroimaging and morphologic methods. The increase of knowledge about depression is reflected by national and international scientific organizations such as the European Depression Association.

The following fields of research are the main areas of interest:

Epidemiological Aspects

The prevalence and clinical phenomenology of depression in specific populations, different cultures, in couples and families and the influence of age, gender and psychosocial factors have been investigated (Gotlib and Hammen 2009). Other topics are its economic cost, the onset and course of depression and longitudinal investigations using interview-based and self-reported measures as outcomes of depression (Freeland and Carney 2009). Furthermore, there is increasing knowledge regarding the relationship between depression and medical illness, medical illness as a predictor of depression, as a cause of depression and depression as a predictor of the onset of medical illness and as a risk factor for morbidity and mortality (Freeland and Carney 2009).

Neurobiological Aspects

MDD is a heterogeneous clinical entity and is associated with a wide range of trait- and state-dependent neurobiological instances (Thase 2009). Research on the neurobiology of depression began in the late 1950s. The research methods focus on transmitter and endocrine

systems, peptides, sleep and circadian rhythms, electrophysiology, anatomical imaging (see chapter ► [Neuroimaging](#)) and pathologic and animal studies to examine the underlying neural basis of mood and emotion. Increasingly, powerful molecular genetic methodologies are being applied in order to find genetic sequence variations that increase one's risk of developing depression (Levinson 2009).

Psychological Aspects

There are links between depression and prenatal stress, inadequate parenting, abuse and neglect, early trauma, loss of a parent, social environment and life stress (Goodman and Brand 2009). The nature of cognitive processes in depression is vital for our understanding of the beginning and the maintenance of MDD (Joormann 2009).

Treatment of Depression

In randomized blinded placebo-controlled multicenter clinical trials, the efficacy of prevention and treatment of depression with pharmacotherapy, cognitive behavioral, family and interpersonal therapy, psychosocial intervention and combined approaches were investigated (Gotlib and Hammen 2009).

Characteristics

The German system of psychiatric services is separated into psychiatry and psychosomatic subdisciplines (Diefenbacher 2005). A lack of empirical evidence means it is not possible to assess the advantages and/or shortcomings of these two subdisciplines (Diefenbacher 2005). There is an overlap between the focus of interest and methods used in psychiatry and affective neuroscience in relation to the neurological discipline (Diefenbacher 2005). Recent developments in psychiatry have gained a better insight into the biological basis of psychiatric disorders (Northoff 2008). The concept of neuronal integration may bridge the gap between localization and holism of functions and brain regions (Northoff 2008). The dimensions of the

mind-brain relationship remain an area of interest for psychiatry irrespective of the progress in research on the biological basis of mental disorders (Slosarczyk 2005).

Relevance to Science and Religion

“The role of cognitive processes in the religious experience should be a focus of neuroscience” (Fingelkurts and Fingelkurts 2009). The key question on this topic is “Is our brain hardwired to believe in and produce God, or is our brain hardwired to perceive and experience God?” (Fingelkurts and Fingelkurts 2009). Aspects of religious beliefs may overlap with neurotic and psychotic symptoms, sometimes making it difficult to determine whether they are a resource or a liability (Koenig 2009).

The recent findings of a prospective neuroimaging study ($N = 268$) measuring hippocampal volume change indicates that hippocampal atrophy in late life may be influenced by certain types of religious factors (Owen 2011). “Significantly greater hippocampal atrophy was observed for participants reporting a life-changing religious experience” (Owen 2011). Hippocampal volume has been linked to clinical conditions, such as depression (Owen 2011).

Recent studies have shown that religion can serve as a psychological and social resource for coping with stress (Koenig 2009). Religiosity and other factors such as the availability of supportive others, access to health care systems, short-term plans for the future, a strong therapeutic alliance, problem-solving skills, are recognized protective factors of depression and can protect people from suicide (Chentsova-Dutton and Tsai 2009). Religion stabilizes the social network whereas the lack of stable and supportive social relationships is associated with a heightened level of depressive symptoms and increased prevalence of major depression across cultural groups (Chentsova-Dutton and Tsai 2009).

Many studies have shammed a negative relationship, that is, the more religious, the lower the depression. Greater religiosity may contribute

to development of resilience to depression in high-risk individuals (Kasen 2011). Increased religious attendance was associated with significantly reduced frequencies for mood disorder (by 43%) in all offspring (Kasen 2011). The relationships between religiosity and mental health were stronger in males and older adolescents than for females and younger adolescents (Wong 2006).

Religion can be split into extrinsic aspects relating to religious rituals and intrinsic aspects showing high levels of spirituality (Nelson 2002). During a trial of 162 patients in palliative-care facilities with a life expectancy <6 months, despite a strong negative association between spirituality and depressive symptoms, no such relationship was found between religiosity and depressive symptoms (Nelson 2002).

However, there was a lower tendency of elderly people with religious affiliations to seek treatment for mental health problems seen in the National Mental Survey of Elderly Singaporeans in 2004. Compared to those with no religious affiliation, elderly people of all religious beliefs showed higher prevalence of mental health problems, yet reported less frequent treatment to health care professionals (Ng 2011).

Sources of Authority

Emil Kraepelin, the German psychiatrist, pioneered the classification of psychiatric disorder early in this century (Hirschfeld and Goodwin 1988). He researched both longitudinal history and the pattern of current symptoms. He proposed that manic-depressive illness “constituted a genetic spectrum of disorders” (Hirschfeld and Goodwin 1988). The American Adolph Meyer saw psychiatric disorders as “primarily the outcome of interactions between the individual and the environment” (Hirschfeld and Goodwin 1988). In 1957, Karl Leonhardt, another German psychiatrist, proposed that manic-depressive illness be separated into bipolar and monopolar disorders. (Ian H. Gotlib and Constance L. Hammen 2009) edited the “Handbook of

Depression,” and this handbook shows the broad and diversified nature and development of the science surrounding depression.

Ethical Principles

The care management of a depressive individual with suicidal ideas could lead to an ethical dilemma. The therapist has to decide between safety and freedom of the suicidal patient.

Good clinical practice (GCP) is an international ethical and scientific set of standards for designing, conducting, recording and reporting trials that involve the participation of human subjects. Compliance with this standard provides public assurance that the rights, safety and well-being of trial subjects are protected, in line with the principles that originate in the Declaration of Helsinki (Good Clinical Practice 2002). The conditions under which placebo-controlled trials in depressives are ethical have to be defined (Laughren 2001).

Key Values

The research of depression requires conceptual and operational definitions. It has to consider third-variable confounding factors, physical comorbidities and interacting comorbidities. Cultural factors, race, gender and age are just some of the factors that influence the course of the illness. Research has been carried out on the onset, response, remission, recovery and treatment effects (Ingram and Siegle 2009). An understanding of causal issues and the risk of recurrence and relapse is needed.

Conceptualization

World

From a clinical perspective, unprecedented migration being a core dimension of contemporary globalization, poses new challenges to global health on a macro and micro scale.

In a *world* of increasing human mobility, there are many new outcomes on health influenced by transnational interactions between care providers and care recipients (Koehn 2006).

Human Being

A living *human being's* life experiences are “a dynamic interaction between the environment around, the environment within and the different forms of consciousness” (Fingelkurts and Fingelkurts 2009). The human is seen as “a psycho-somatic entity consisting of multiple levels and dimensions of human existence (physical, biological, psychological and spiritual reality), allowing consciousness/mind/spirit and brain/body/matter to be seen as different sides of the same phenomenon” (Fingelkurts and Fingelkurts 2009).

Life

Life changes occur as part of passing from one stage to another during the course of maturation and development and in particular the behavior and role-function adaptations that an individual is required to make in response to age-related changes over which he or she has little, if any, control (WHO Library Cataloguing in Publication Data 1994).

Reality

“The perception of living human *reality* is regulated by the environment around, the environment within and the consciousness that helps him make sense of both” (Fingelkurts and Fingelkurts 2009).

Knowledge

“To *know* yourself, your purpose of life and talents and taking these into full use and becoming coherent with life inside and reality outside is what human life is essentially about” (Ventegodt et al. 2005).

Truth

Evidence-based medicine supports validated strategies. Science tries to force “the *truth* way” of treatment. Science is strategically planned and uses a method described as principle-based concept analysis (Penrod and Hupcey 2005).

Perception

Neuronal oscillations of different frequencies are hypothesized to be basic for *perception* (Pöppel 2009). Perceptual scientists have recently enjoyed success in constructing mathematical theories for specific perceptual capacities (Bennett 1991).

Time

The subjective experience of *time* is a fundamental constituent of human consciousness and can be disturbed under conditions of mental disorders (Vogeley and Kupke 2007).

Consciousness

Consciousness consists of the following: A default consciousness, which is “a primary default state differentiating the living from the dead and the non-living” (Singh and Singh 2011). Consciousness also consists of a state of aware consciousness which includes the different stages from awake to sleep, including drowsy, dreamy, non-dreamy, etc., as well as altered states such as delirious, comatose, illusionary, hallucinating, etc. (Singh and Singh 2011). Consciousness is also a state of operational consciousness wherein all observable/unobservable brain operations like cognition, perception, emotion, conation, etc., result (Singh and Singh 2011). Consciousness is, finally, also a state of exalted consciousness wherein the brain establishes a link with the “inner self,” the divine, God, soul, etc. (Singh and Singh 2011).

Rationality

Human decisions cannot be explained solely by *rational* imperatives but are strongly influenced by emotion (Coricelli et al. 2007). Convergent evidence demonstrates the varying contributions of various regions of the prefrontal cortex to cognitive control (Ridderinkhof et al. 2004). Theoretical and behavioral studies provide an empirical basis to the impact of the emotion of regret in guiding choice behavior (Coricelli et al. 2007).

Mystery

The corresponding activities of the neural network occur only in harmony with physical laws;

however, this fact does not necessarily imply that there can be a comprehensive scientific theory of consciousness, despite all the progress in neurobiology, neuropsychology and neurocomputation (Gierer 2008). The brain-mind relationship may never be fully “decodable” and may remain a *mystery* (Gierer 2008). Objective analysis by the methods of natural science cannot, in principle, fully encompass subjective, mental experience (Gierer 2008).

Relevant Themes

A critical issue in Psychiatry and Depression regarding “Science and Religion” is the notion of culture and the different religious affiliations. Although depressive disorders occur across all demographic groups, cultures and ages, their manifestations, meanings, treatments and possible causes may differ significantly from one population to another (Chentsova-Dutton and Tsai 2009). “Culture (e.g., religions, values, norms) shapes behaviour, thoughts and emotions of individuals and is in turn shaped by them” (Chentsova-Dutton and Tsai 2009). The impact of depression on emotional response varies depending on the dominant cultural model of healthy emotional functioning (Chentsova-Dutton and Tsai 2009).

Depressive Episode

Joachim Cordes

LVR Klinikum Düsseldorf, Düsseldorf, Germany

A disease state manifesting the features of depression which may be specified as mild, moderate, or severe, depending on the intensity and number of symptoms. The severe form may further be subdivided according to the presence or absence of mood-congruent or mood-incongruent psychotic symptoms.

Recurrent Depressive Disorder

A disorder characterized by repeated depressive episodes without any history of independent episodes of mania but not excluding brief episodes of hypomania immediately after a depressive episode.

Description

Determinism and indeterminism are large-scale doctrines about the nature of reality. Roughly

speaking, determinism is the doctrine that all past, present, and future events – including all acts of the will and all occurrences in nature – are determined and cannot but take place in the way they take place. Indeterminism is the negation of determinism; to deny determinism is to affirm indeterminism.

Versions of determinism and indeterminism have been around for millennia. One of the oldest known forms of determinism is theological determinism. In more recent centuries, it is physical determinism that has attracted the most philosophical attention. In what follows we will survey some main forms of theological and physical determinism and indeterminism, along with their underlying motivations, some of their main difficulties, and some of their mutual interrelations.

Theological Determinism

Theological determinism consists in the belief, roughly put, that there is one unique way in which the world (including human history) will unfold, and that this one unique way has, prior to its unfolding, been “fixed” by a deity or Ultimate Reality of some sort. There is not one but various “theological determinisms,” however. Theological determinisms differ from each other by virtue of the nature of the relevant deity; the deity can be believed to be the God of classical theism, Zeus, Fate, the stars (construed as divine beings), and so on. Theological determinisms also differ from each other by virtue of the way in which the relevant deity is believed to have fixed the one unique unfolding of the world; it could be by divine decree, causation, permission, concurrence, or foreknowledge (or combinations of these), and so on. A third way in which theological determinisms differ from each other pertains to the role that human beings and/or other agents are believed to play in the unfolding of the one unique story of the world – Do they play an active role in this story, contributing something to it by their volitions and actions? Or are they, say, mere puppets, subject to an illusion of free volition and action but lacking the real thing?

A major representative of theological determinism in Western thought is Augustine of

Hippo (354–430). In a famous passage in *De civitate Dei* (i.e., I.V.9–10) Augustine upholds two seemingly contradictory doctrines: first, that God has fixed a unique order of events (*omnium ordo causarum*) according to which the world will unfold ([c. 413–427] 1963, 174); and second, that human beings notwithstanding this fixed order of events have free will (*voluntatis arbitrio*) ([c. 413–427] 1963, 176).

The main sources of motivation for both doctrines are largely theological. The motivation for the first doctrine is provided for by the doctrine of divine foreknowledge. Since Augustine, qua orthodox Christian, believes that God knows everything and hence also all future events, it follows that he is committed to the belief that there is one unique way in which the world will unfold, namely, the way foreseen by God. The main motivation for the second doctrine is provided for by considerations pertaining to moral responsibility and the appropriateness of punishments and rewards. Since Augustine, qua orthodox Christian, believes that moral responsibility exists and that punishments and rewards are appropriate, and given that moral responsibility, on the part of human beings, presupposes that human beings act not under compulsion but out of free will, it follows that Augustine is committed to the belief that human beings have free will.

Augustine is aware that there at least seems to be a tension between the above two doctrines, and so he adduces various considerations that show, or purport to show, that the two doctrines do not conflict with each other. A first such consideration is that human volition is dependent on God in that human beings cannot will anything if God's will does not first permit that they will be the thing in question. A second consideration is that in connection with a human being's act of willing to do something, God is the one who grants the power which translates the volition into the action in question. A third consideration is that human volitions are part of the order of events which constitutes the one unique unfolding of the world.

Although the above considerations yield an understanding according to which free will and determinism are compatible, it should be borne in

mind that it is a specific kind of free will and a specific kind of determinism that are here spoken of. The conception of free will at play in Augustine's reasoning is a conception according to which a person acts out of free will if he or she does what he or she wills to do, and the conception of determinism at play is one according to which everything that happens cannot but happen since God in his foreknowledge has already seen it happen.

A second major representative of theological determinism in Western thought is the Protestant Reformer Martin Luther (1483–1546). In his much-read and controversial book *De Servo Arbitrio* (1525), Luther upholds, among other things, the following two doctrines: first, that “all things happen according to God's immutable, eternal, and infallible will” (*omnia incommutabili et aeterna infallibilique voluntate et praevidet et propouit et facit*) ([1525] 1908, 615); and second, that this entails that human beings lack “free will” (*liberum arbitrium*) ([1525] 1908, 615).

The motivation for both of these doctrines is theological. The first doctrine is supported by considerations deriving from divine foreknowledge. Luther argues that since God foreknows all things that happen and since all things that are foreknown are foreknown according to God's immutable, eternal, and infallible will, it follows that all things happen according to God's immutable, eternal, and infallible will. The second doctrine is taken to be a corollary of the first doctrine (although Luther also seeks to support it by independent biblical proof-texts): since all things happen according to God's immutable, eternal, and infallible will, there can be no such thing as human free will.

Luther claims that his above position is in agreement with the position of Augustine ([1525] 1908, 640). At first sight this might only seem to be partly true: Luther's first doctrine, that all things happen according to God's will, seems to agree with Augustine's doctrine that there is a fixed order of events that God has foreseen and caused to be; but Luther's second doctrine, that divine foreknowledge entails that human beings

lack free will, seems to be the very opposite of Augustine's claim that divine foreknowledge is consistent with the claim that human beings have free will.

The apparent conflict between Augustine's affirmation and Luther's denial of human free will is only apparent, however. As Luther makes clear, in denying the existence of human free will he is using the expression "free will" in the sense of "a power of freely turning in any direction, yielding to none and subject to none" (*possit in utrunque se vertere, neque ea vis ulli caedat vel subiecta*) ([1525] 1908, 637). And he also makes it very clear that he is not denying that human beings act not under compulsion but willingly and spontaneously (*sponte et libenti voluntate*) ([1525] 1908, 634). So Luther's denial of human free will is a denial of man's ability to will and to act without being subject to an overriding divine will; and this denial is in full agreement with Augustine's position. Moreover, Augustine's affirmation of human free will is an affirmation of the spontaneous willing and non-coerced nature of human action, and this affirmation is in full agreement with Luther's position. Thus, although Augustine and Luther employ different terms and phrases, their respective positions are nonetheless in fundamental agreement. They both subscribe to a form of theological determinism according to which God's attributes or actions ensure that all things cannot but unfold in one unique way, and that human volition and action cannot alter this one unique way, although this does not mean that human volition and action is non-spontaneous or coerced.

Theological determinism has been objected to on various grounds. A common objection is that the position is theologically defective in that it renders genuine love of God impossible. Genuine love, it is said, is always free and never subject to necessity, theological, or otherwise. If so, then genuine love of God cannot exist in a world in which all events are already determined. So in order for it to be possible to genuinely love God, theological determinism must be false.

Another objection to theological determinism has it that the position renders many religious

practices unintelligible. Take prayer, for example. What point is there in praying to God to intervene in some worldly event if it is already determined what will take place? It was partly in response to such questions that the classical philosopher Gottfried Wilhelm Leibniz (1646–1716) – himself a Lutheran – wrote his *Theodicy* (1710), in which he retorted that if an event is determined beforehand then the cause of the event (e.g., which can be divine intervention in answer to prayer) must also be determined, in which case there is all the point in the world to keep praying (e.g., Leibniz [1710] 1952, 57).

Theological Indeterminism

A theological indeterminist can be described as someone who believes that there exists a deity but who denies that this belief entails one unique story of the unfolding of the world. There are two basic ways of harmonizing the relevant belief with the relevant denial.

A first attempt to harmonize the belief in a deity with the denial of a fixed order of events consists simply in denying that God has foreknowledge of all future events, which, as we have seen, functions as a main rationale for theological determinism. This strategy was adopted by some ancient philosophers, including Marcus Tullius Cicero (106–43 B.C.), and has recently been revived in contemporary Anglo-American philosophy of religion by the so-called Open theists such as William Hasker (1989). A core tenet of Open theism is the belief that the future is not fixed, which is taken to be allowed for partly by denying that God has foreknowledge of all future events and partly by affirming that human beings have libertarian free will (i.e., a will that is able to select between equally possible courses of action unrestrictedly).

A second attempt to harmonize the belief in a deity with a fixed order of events consists in arguing that divine foreknowledge simply does *not* entail that there is one unique story of the unfolding of the world. This strategy has been fleshed out in various different ways. One such way, endorsed for example by Alvin Plantinga (1986), consists in introducing a distinction

between “hard facts” which hold necessarily, and “soft facts” about the past, which hold only contingently, and then arguing that God’s foreknowledge is of the category of a soft fact, and hence is a contingent matter. This has been held to allow for indeterminacy in the world.

The main motivation or theological indeterminism derives in large part from a belief in the existence of libertarian free will. That is, it is believed that human beings have the ability to select between a variety of equally possible courses of action, without being subject to any overriding divine or non-divine will. Given this belief, an admission of some sort of indeterminacy in the world and in God’s dealings with the world seems warranted.

Critics of theological indeterminism have often sought to undermine the position by arguing either that God does have foreknowledge of all future events, or that the various attempts to harmonize divine foreknowledge with indeterminacy in the world are untenable. The first strategy is pursued mainly against theological indeterminists like Hasker who deny divine foreknowledge, and the second strategy is pursued mainly against theological indeterminists, like Plantinga, who concede divine foreknowledge but deny the inference of theological determinism.

Physical Determinism

In the seventeenth and eighteenth centuries, a new form of determinism gained momentum and subsequently replaced theological determinism as the main form of determinism in philosophical discussions, namely, *physical determinism*. Indeed, physical determinism has so come to dominate philosophical discussion that many contemporary philosophers use the term “determinism” as more or less equivalent to what we are here calling physical determinism, often regarding theological determinism as “a mere historical puzzle” or “intellectual amusement” (Dennett 1984, 171).

That physical determinism gained momentum in the seventeenth and eighteenth centuries was connected in part with the emergence of Newtonian physics. Newtonian physics, and in

particular its claim, that all physical, material phenomena move mechanically by virtue of laws of nature, encouraged deterministic ways of thinking. For if one grants that human beings are material, physical phenomena the obvious conclusion is that also human behavior is entirely determined by laws of nature.

Drawing on the idea of laws of nature, the following influential definition of (physical) determinism has been offered: “*Determinism*... is the thesis that there is at any instant exactly one physically possible future” or again: “given the past and the laws of nature, there is only one possible future” (van Inwagen 1983, 3, 65). The number of philosophers subscribing to determinism, understood roughly along lines of this definition, seems to be vast, and includes, among others, the Enlightenment philosopher David Hume (1711–1776), logical positivists of the mid-twentieth century such as Moritz Schlick (1882–1936), and a large company of contemporary analytic philosophers, among which perhaps Daniel Dennett is the most prominent.

The main motivation for physical determinism seems to be that it is the natural outcome of a naturalistic world-view. On a naturalistic world-view, human beings are understood as entirely natural, physical, and biological phenomena, and like all natural, physical, and biological phenomena their motion or behavior is to be understood as the outcome of the operation of the laws of nature. This natural outcome, it seems, can only be avoided by positing some immaterial extra component in human beings – a “soul,” for example – or by denying that the motion or behavior of material, physical, and biological phenomena can be fully explained via reference to operations of the laws of nature, both of which strategies seem to fit ill with a naturalistic world-view.

There are at least four major types of objections to physical determinism in the contemporary philosophical literature, deriving from considerations pertaining to free will, morality, what is up to human beings, and quantum mechanics respectively. In what follows we will survey each of these three major types of objections.

A first objection to physical determinism derives from considerations pertaining to free will, and goes roughly as follows: If physical determinism were true, then human free will could not exist, for human free will requires that a person is able to select one of several possible courses of action, which would not be possible if physical determinism were true. But we know from human experience that human beings have free will, and so physical determinism must be false.

A second objection to physical determinism derives from considerations pertaining to morality, and goes roughly as follows: If physical determinism were true, then there could be no such thing as genuine human morality and responsibility, for genuine human morality and responsibility requires that human beings could have done otherwise than they in fact did. But there *is* such a thing as genuine human morality and responsibility, and so physical determinism must be wrong.

A third and in recent times much-discussed objection to physical determinism is the so-called Consequence-argument of Peter van Inwagen, which draws on considerations pertaining to what can be said to be “up to” human beings and what cannot. The argument goes roughly as follows: Physical determinism entails that human actions are the consequences of the laws of nature and events in the remote past. But it is not up to us what the laws of nature are and what events went on in the remote past. Hence, the consequences of the laws of nature and events in the remote past cannot – in contrary to what physical determinism implies – be up to us (see van Inwagen 1983, 16).

A fourth objection to physical determinism draws on modern scientific theory, and, in particular, a central postulate of quantum mechanics which allows for indeterministic properties on the part of submicroscopic, subatomic particles. If this postulate of quantum mechanics is correct, it may be wrong to say that the behavior of all material phenomena is determined by laws of nature, for there will then be at least one kind of material phenomena that may not thus be determined.

Physical Indeterminism

Like theological indeterminism, physical indeterminism is a negative position, and can be defined as the negation of physical determinism. Accordingly, if physical determinism is defined, as in the foregoing, as the thesis that given the past and the laws of nature there is only one possible future, physical indeterminism can be defined as the denial of this thesis. Physical indeterminism is, thus, consistent with the claim that given the past and the laws of nature there are several possible futures. One of the most prominent contemporary representatives of physical determinism is the aforementioned van Inwagen.

There are at least three main sources of motivation for contemporary physical indeterminism. A first source of motivation is provided for by human free will. It is maintained that human beings have free will and that free will entails that human beings have the ability to choose between two equally possible courses of action, or alternatively put, an ability to have done otherwise than one in fact did. But if one is to have the ability to choose between two equally possible courses of action or to have done otherwise than one in fact did, then physical determinism must be false and hence physical determinism be true. So given that free will exists, physical indeterminism must be true.

A second source of motivation for physical indeterminism is provided for by human morality and could be regarded as an adaptation of the first source of motivation. It is maintained that morally significant human acts require that human beings could have acted otherwise than they in fact acted (a principle often called “the Principle of Alternate Possibilities”). But if it is to be possible that one was able to have acted otherwise than one in fact acted, then physical determinism must be false and hence physical indeterminism be true. Accordingly, given that human morality exists, it follows that physical indeterminism must be true.

A third source of motivation for physical indeterminism derives from quantum mechanics. Since, as has been said earlier, a central postulate of quantum mechanics allows for indeterminacy

in the world, it is judged that physical determinism is probably mistaken and hence physical indeterminism probably true.

The above sources of motivation for physical indeterminism have not gone unchallenged, however, and especially the first and second sources of motivation have been subjected to much criticism. In what follows we will survey two major objections against each of these two sources of motivation.

A first objection against the first above source of motivation consists in the claim that free will does *not* entail an ability to choose between two equally possible courses of action. According to Hume's famous definition, for example, free will consists simply in a certain "liberty of spontaneity," which is defined as "that which is opposed to violence" (Hume [1739–40] 2009, 262). That is to say, a person acts out of free will if he or she acts not under compulsion but willingly. Given this alternative conception of free will, it is simply false to say that free will entails an ability to choose between equally possible courses of action.

A second objection to the first above source of motivation consists in a so-called conditional analysis of the phrase that one "could have done otherwise" than one in fact did. At first sight it might seem that phrase of this sort require an "ability" on the part of free agents to select between two possible courses of action. Against this, G.E. Moore (1873–1958) famously argued, in his book *Ethics* (1912), that the relevant sort of phrases seem rather to be analyzable in terms of conditionals, such that, say, the phrase "Peter could have refrained from eating lunch" is analyzable in terms of the conditional "if Peter had willed to refrain from eating lunch, he would have refrained from eating lunch." Given this style of analysis, it seems false to say that free will requires an ability to have selected an alternative course of action from the course one actually selected.

Turning to the second above source of motivation for physical indeterminism, we may note the following three major objections: A first objection takes issue with the idea that moral responsibility requires an ability to have acted

otherwise than one actually acted. In a famous paper from 1969, Harry Frankfurt adduces various intuitively appealing thought-experiments which aim at undermining this principle (nowadays known as "Frankfurt-counterexamples"). Imagine, for example, that a certain man called Black is able to manipulate the brain of a certain man called Jones in such a way as to be able to prevent Jones from carrying out any action that he, Black, does not want Jones to carry out. Suppose further that Jones performs a series of actions that we would ordinarily consider are morally significant – whether good or bad makes no difference – without Black preventing this. Would we say that Jones is morally responsible for these actions? It seems we would. But then note: Black could have prevented Jones from carrying out any other series of actions than the series of actions he actually carried out, and so Jones cannot be said to have been able to have acted otherwise than he in fact acted (see Frankfurt 1969). Many philosophers have judged these sorts of counterexamples thoroughly persuasive, and have accordingly rejected the Principle of Alternate Possibilities as mistaken.

A second major objection to the second above-mentioned source of motivation denies that the question of whether one could have acted otherwise than one in fact acted is even *relevant* to the question of the morality of an action. This is the position of Dennett in his much-discussed book *Elbow Room* (1984). The answer to the question whether one could have acted otherwise than one did, says Dennett, "could not conceivably make any noticeable difference to the way the world went" (1984, 138). The basic idea here is that sufficient conditions for the moral status of an action are located in the action itself, irrespective of whether the action was one of several possible actions that the subject could have performed. If Dennett's reasoning on this point is correct, then the Principle of Alternate Possibilities will be mistaken and the presently considered second source of motivation for physical indeterminism will be undermined.

A third major objection to the second above-mentioned source of motivation for physical indeterminism takes issue with the very idea

that human beings are genuinely responsible for their actions. In his book *Freedom and Belief* (1986), Galen Strawson has developed a powerful argument for the claim that human beings are not genuinely responsible for their choices and actions. The argument goes roughly as follows: The choices one makes and the actions one performs are largely a function of one's character; in order to be fully or genuinely responsible for one's choices and actions one must accordingly be fully or genuinely responsible for one's character; but in order to be fully or genuinely responsible for one's character one must have chosen to be the way one is; however, no one has ever chosen to be the way one is; accordingly, no one is genuinely responsible for his or her choices and actions (see Strawson 1986, 28–29). If Strawson's present argument is cogent, then the presently considered source of motivation for physical indeterminism will be subverted.

Interrelations Between Theological and Physical Determinism

Among the various similarities between theological and physical determinism, the following two are particularly interesting.

First, both theological and physical determinism are in agreement that the events of the world cannot but unfold in exactly the way in which they unfold. There is simply no other genuine possibility: either a certain event has been foreseen or it has not been foreseen, or will result from the operation of the laws of nature on matter or will not thus result, and so it is either necessary that it takes place or it is impossible that it takes place. In other words, the unfolding of the world is already fixed.

Second, both theological and physical determinism are typically associated with a non-libertarian, compatibilist understanding of human volition. Thus, it is not surprising to find that major representatives of theological and physical determinism, such as Augustine and Hume, in spite of all their differences, nevertheless, agree in taking human free will to consist in a subject's not acting under coercion but rather doing what he or she wills to do.

Among the more noticeable differences between theological and physical determinism, the following two are worth pointing out.

First, theological determinism can be seen to allow for a greater variety of possible causes of action than physical determinism. Physical determinism sees actions as caused exclusively by the operation of laws of nature on material phenomena; theological determinism allows for such causes, but allows equally for agent causation (both human and divine), and for further kinds of causation as well (if such there be).

Second, theological determinism takes the one unique and fixed way in which the world unfolds to be ensured by a deity, and hence to allow for an element of teleology or goal-directedness. Physical determinism, on the other hand, takes the laws of nature and the existence of matter to be sufficient determinants for the one unique unfolding of the world, and hence allows for no teleology or goal-directedness in this unfolding.

Deterministic and Nondeterministic Turing Machine

Gómez González Daniel
 Universidad Complutense De Madrid,
 Madrid, Spain

A Turing machine is a theoretical machine that manipulates symbols on a strip of tape according to a table of rules. Despite its simplicity, a Turing machine can be adapted to simulate the logic of any computer algorithm and is particularly useful in explaining the functions of a CPU inside a computer. In computational complexity discipline, a deterministic Turing machine is a theoretical machine that is used in thought experiments to examine the abilities and limitations of algorithms. In a deterministic Turing machine, the set of rules impose at most one action to be performed for any given situation. In a nondeterministic Turing machine, it may have a set of rules that prescribes more than one action for a given situation.

Developmental Psychology

Richard M. Lerner¹ and Jacqueline V. Lerner²

¹Eliot-Pearson Department of Child Development, Institute for Applied Research in Youth Development, Tufts University, Medford, MA, USA

²Department of Counseling, Developmental, and Educational Psychology, Lynch School of Education, Boston College, Chestnut Hill, MA, USA

Description

Developmental psychology involves the description, explanation, and optimization of intraindividual change and of interindividual differences in such change (Baltes et al. 1977). The study of development involves seeking to describe, explain, and optimize the course (trajectories) of such changes and, as well, of interindividual differences in intraindividual change across the life span. In other words, there are three goals of the science of developmental psychology: (1) describe the nature of development for individuals and groups, (2) explain the nature of development for individuals and groups, and because of the interest in using developmental science to improve the human condition, (3) optimize, as much as possible, the trajectories of development. Here, then, the key questions for developmentalists are what characteristics of people and what attributes of the environment need to be engaged in what manners and during what portions of the life span to increase the probability that individuals will thrive across the life span (Lerner 2002)?

As suggested by the focus of questions about optimization on both the individual and his or her environmental setting, today, the cutting edge of developmental psychological theory sees development as involving mutually influential relations between the individual and his or her context. That is, the fundamental, or basic, process of development is a *relation* between individual and context. As such, development is

neither an individual “unfolding,” for example, due to genetic influences, and it is not a consequence of an environmental molding of an essentially passive organism. Accordingly, the focus within the contemporary study of human development is on concepts and models associated with relational developmental systems theories.

Such theories focus on the *mutually influential relations* among variables from the multiple levels of organization (ranging from the biological through the sociocultural and historical) that comprise the ecology of human development. These relations may be termed dynamic interactions or developmental regulations, which intends the mutual influence between one variable within the developmental system and another variable or variables within the developmental system, and they are typically represented as individual $\longleftrightarrow$ context relations. The inclusion of history within these theories provides a temporal component to the system and gives the system a basis for change. Indeed, historical embeddedness and temporality are among the defining features of contemporary relational developmental systems theories of human development. Other concepts are relationism, which is the idea that the fundamental character of life involves relations among entities, that to be is to be in relation, and that there are no entities split off or isolated in their structure or function from relations with the other components of the ecology of life; the integration of levels of organization, i.e., the components of the ecology of development, ranging from micro tiers (e.g., levels within a person, such as his/her genes, brain, or cognitive or emotional characteristics) through macro tiers (e.g., society, culture, and historical era); relative $\blacktriangleright$ [plasticity](#) (the potential for systematic change in structure or function across life), $\blacktriangleright$ [diversity](#), and $\blacktriangleright$ [self-organization](#) (Overton 2006).

Self-organization arises because dynamic interactions within a developmental system involve a dialectic between system-changing and system-constraining relations. Such a balance between changes that make the system different and changes that maintain the structure

and function of the system reduces the potentially infinite complexity of the system and, as such, enables the identification of continuous instances of structure and function. In short, change across the life span occurs within a dynamic developmental system that creates both constancy and variation.

As marked by differences across the six editions of the most important reference work in the field, the *Handbook of Child Psychology* (1946, 1954, 1970, 1983, 1998, and 2006), the current emphasis within this subdiscipline on relational developmental systems theories, reflects a remarkable change in the predominant theoretical foci used to study human development (Damon and Lerner 2006). There has been a change from reductionist accounts that stressed the development arose from either nature (e.g., genes) or nurture (e.g., environmental stimuli), or from simplistic combinations of variables associated with nature or nurture, to the above-noted focus on mutually influential, individual $\longleftrightarrow$ context relations emphasized within contemporary relational developmental systems theories.

These changes in theoretical models within the field have resulted in another major change, one involving the professional identity of scientists working in this field. A decade ago, most scholars studying human development labeled the field as either developmental psychology or, if they were not themselves psychologists, as a field wherein one had to recognize that psychological science was the predominant lens through which the span of human life was studied. Today, however, the field has become much more deeply and broadly multidisciplinary (and, in some subareas, actually interdisciplinary or, in other words, disciplinarily integrative, for example, developmental cognitive neuroscience). As a consequence, more and more scholars of human development refer to their field as developmental science (Bornstein and Lamb 2010). Developmental science seeks to describe, explain, and optimize changes across the life span in within-person change and differences between people in within-person change.

The change of name for the field studying the human life span reflects in large part a key

intellectual change that we have noted is reflected across the various editions of the *Handbook of Child Psychology*: the certain “demise” of split conceptions of the nature-nurture issue and of reductionistic approaches to either nature formulations (sociobiology or behavior genetics) or to nurture formulations (e.g., approaches that attempt to account for development through reference to stimulus-response relations or through an analysis of the function of stimuli); the ascendancy of focus on relational developmental systems models, conceptions that seek to fuse systemically the levels of organization involved in the ecology of human development (from biology and physiology through culture and history; and the emphasis on relations among levels and not on the “main effects” of any level itself, as constituting the fundamental units of analysis of developmental analysis).

Indeed, as illustrated by the range of chapters in the 2006, sixth edition of the *Handbook of Child Psychology* that are an instance of or, at the least, are framed by developmental systems ideas about the relational processes linking the multiple, integrated levels of organization within the ecology of human development, there exists a diverse theoretical family of such models that are used to conceptualize both “traditional” areas of interest within the study of human development, for example, biological development; perceptual and motor development; personality, affective, and social development; culture and development; cognitive development; and “emergent” areas of intellectual interest, for example, the development of diverse children, positive human development, and – of particular relevance to this encyclopedia – spiritual and religious development (Damon and Lerner 2006).

These theoretical emphases on individual $\leftrightarrow$ context relations within developmental science fortunately have been coupled with enormous, recent advances in quantitative statistical approaches, arguably especially in regard to the longitudinal methods required to appraise the changing relations within the developmental system between the individual and the context. Moreover, there has been an increased appreciation of the importance of qualitative methods,

both as valuable tools for the analysis of the life course and as a means to triangulating quantitative appraisals of human development; as such, there has been a growth in the use of traditional qualitative methods, along with the invention of new qualitative techniques (Baltes et al. 1977; Lerner 2002).

Finally, it should be noted that this exciting and innovative period in developmental theory and methodology has been framed by a renewed appreciation of the importance of the application of theory-predicated research to promote positive development across the life span. Increasingly, then, across the last two decades, developmental scientists have been involved in conducting research that informs, testing ideas associated with, or evaluating policies or community-based programs aimed at enhancing the lives of diverse individuals, families, and communities.

Self-identification

Science

Yes. Developmental science rests on a commitment to the scientific method and, hence, to empiricism. Indeed, the identity of the field, reflected by preference for labeling the field as developmental science, involves an explicit commitment of the field, and of the scholars working within it, to science.

The subdiscipline is a field of science that, as noted, rests on empiricism. Accordingly, the epistemology of developmental science is framed by empiricism and the other core components of the scientific method – systematic and purposeful observations, replication, communication, correction, and the accumulation of knowledge. The ontology of developmental science is also predicated on empiricism, that is, to be is to be capable of observation. Entities that cannot be made empirical or in some way made available to observation cannot be useful within this ontology. Because current beliefs within developmental science about explanation, and hence about causality, emphasize the centrality of falsification, causal statements for which there are no empirical referents – for which there are no

possible observations that can falsify the statement – are not part of the science (Overton 2006).

Of course, concepts such as spirit, grace, or holiness can be operationalized, thus, made empirical, and thereby become available to be the focus of scientific study. Therefore, facets of religiosity or spirituality may quite appropriately be topics of inquiry within developmental science. However, when such constructs are part of one's faith – that is, a commitment to a belief that does not require empirical verification and is not subject to empirical falsification – they are not part of science. These terms of faith are part of a nonscientific (but epistemologically equivalent in our view) way of knowing.

In short, many scientists, including developmental scientists, are religious. They may therefore use ideas such as spirit and faith as empirical concepts available for scientific study *or* as concepts linked to their religion. When the latter use of these concepts is employed, these ideas are part of a different system of knowing and being and not components of a scientific approach to knowing and being.

Characteristics

Whereas all development involves change, not all changes involve development. Development involves systematic, organized, and successive changes across the life span in the relations within and among levels of organization within the ecology of human development. No other subdiscipline of psychology, or of social and behavioral science more generally, has this focus on developmental change.

Relevance to Science and Religion

Are there any attributes of human development that are distinct from and, perhaps, evolutionarily discontinuous with the attributes of structure and function found in other species? Arguably, religiosity and spirituality are attributes of humans that have no isomorphic parallel in other species. Moreover, religion – both as

a psychological (cognitive and emotional) facet of human functioning and as an institutional force organizing and shaping human behavior – and spirituality, whether linked to religion or faith or directed to senses of awe or transcendence in regard to involvement in the natural social or physical ecological world, are ubiquitous facets of human behavior and development. In a science aimed at describing, explaining, and optimizing human development, especially when that science is framed by a relational developmental systems approach that focuses on individual $\longleftrightarrow$ context relations, religion and spirituality become essential substantive foci of scholarship.

As noted earlier, this substantive focus was included within the 2006 sixth edition of the major reference work in the field of development science, that is, the *Handbook of Child Psychology*. In addition, religion and spirituality were also a focus within the most recent, 2009, third edition of the also influential *Handbook of Adolescent Psychology*. Similarly in the first edition of the *Handbook of Life-Span Development*, there is also a chapter on the role of religious and spiritual development across the course of human life (Scarlett and Warren 2010).

Sources of Authority

In science, which rests on the communication to the scholarly community of one's empirical work and, therefore, on peer review and correction, and potentially final inclusion of one's work in the accumulated archival record of the field, peer-reviewed publications are the main sources of authority. Developmental science shares this commitment to the authority of peer-reviewed publications.

In addition, when one has attained the stature of being a major contributor to the empirical status of a field, one may be asked by scholarly societies and/or publishers to organize major reference works, contributions that reflect the integrative state of the art of the field and that reflect the maturity and scope of a field. Within developmental science, handbooks – most notably the *Handbook of Child Psychology* and the *Handbook of Adolescent Psychology* – are

exemplars of such reference works, which include also annual reviews or, occasionally, reports from such organizations as the National Academy of Sciences or the National Science Foundation that pertain to human development (Damon and Lerner 2006; Lerner and Steinberg 2009; Eccles and Gootman 2002).

Ethical Principles

The major scholarly organizations with which developmental scientists affiliate – for instance the Society for Research in Child Development, the Society for Research in Adolescence, the Society for the Study of Human Development, the International Society for the Study of Behavioral Development, the Gerontological Society of America, the International Society on Infant Studies, the National Council on Family Relations, the American Psychological Association, and the Association for Psychological Science – all have their own and/or subscribe to each others' detailed ethical guidelines for the treatment of animal and human participants in research and, as well, for the application of developmental science scholarship to professional practice, including clinical programs and consultation to communities or private or public organizations (Fisher 2009). In addition, developmental scientists have to meet the standards of protection of human "subjects" (participants) in their research, as specified by university or research organization Institutional Review Boards (IRBs).

Indeed, grant applications to the United States federal government require that the proposals include a discussion of how the welfare and/or rights of animal or human participants will be protected. Before grants are awarded, the principal investigator involved in grant proposals must show the federal funder that IRB approval for the research has been given. In addition, most American universities require that active researchers gain certification that they are knowledgeable about past and current issues, guidelines, and rules regarding the ethical treatment of human participants in their research.

Key Values

Developmental science adheres to two sets of values. First, the field values science, the scientific method, and the ethical conduct of science (Baltes et al. 1977; Lerner 2002; Fisher 2009). Second, the field values humans as "ends in themselves," that is, as individuals whose lives have intrinsic value and who deserve to have the work of developmental scientists aimed ultimately at optimizing their chances for a positive, healthy life. Certainly, this value on the person as a person is reflected in the optimization objectives of developmental science and, as well, is linked to the value of conducting science in an ethical manner.

Together, then, the two sets of values in developmental science coalesce to create emphases on respect for individual rights, dignity, and freedom on beneficence (on doing no harm and in promoting the good) and on social justice. Developmental science, in directing its theoretical and empirical work to describe and explain the mutually influential links between individuals and their contexts and, then, in testing one's explanations of these individual $\longleftrightarrow$ context relations by trying to alter their course and promote positive development, has an "ultimate" concern with social justice. If changes in the relations between people and their contexts can improve the chances for individuals to lead better lives and if such work can therefore be extended to the diversity of instantiations of individual $\longleftrightarrow$ context relations, a vital portion of the work of developmental science is to apply scholarship to policies and programs to distribute opportunities for healthy positive development justly across the diversity of human development.

Conceptualization

Nature/World

Nature and the world are conceptualized as the breadth of the multiple levels of organization within the ecology of human development. The world is organized into multiple levels of

organization ranging from the inner-biological levels of organization within a person (e.g., genetic, cellular, and organ levels) through groups, communities, societies, cultures, and the physical ecology, all of which are in turn embedded in history, in temporal change (Lerner 2002; Overton 2006).

Human Being

The human is regarded as a distinct – and valued – species within the ecology of human development. A holistic and therefore emergent view of the human exists within developmental science. That is, because the “parts” of the individual (characteristics, such as genes, neurons, personality or cognitive style attributes, behaviors, attitudes, social relationships, etc.) create in their systemic fusion attributes of structure and function that do not exist in the parts in isolation, each person must be understood as an individual and in a holistic and integrative manner. Of course, each person, while possessing such ideographic characteristics, also has characteristics in common with some groups (e.g., other people in his or her family, faith institution, community, or profession) and, as well, some characteristics that are shared by all humans (e.g., the various physical systems such as digestion, respiration, circulation, or reproduction, or the potential for systematic change across life, that is, of “plasticity,” across the life span). Therefore, there is truth in the dictum that each person is (in some respects) like all other people, like only some other people, and like no other person (Lerner 2002; Overton 2006).

Reality

Within development science, reality is defined empirically. Reality is the multilevel developmental ecology of human development.

Knowledge

As explained above, developmental science adheres to an empirical epistemology. As such, knowledge is the set of ideas (theories or concepts), principles, and facts accumulated through the application of the scientific method.

Truth

As also noted earlier, developmental science subscribes to an empirical ontology. Following George Berkeley, for instance, developmental scientists would agree that “to be” is to be perceived, that is, to be capable of empirical identification. What is true then is what we can derive as valid from our empirical observations.

Perception

Perception is a function of the individual (including the scientist). Sensation is reaction to stimulation. In turn, perception is “sensing with meaning,” that is, making cognitive and/or emotional associations to one's sensations. As such, perception involves, first, experiencing stimulation through the avenues of the senses and, second, making an association to what one senses (e.g., the object I see before me is a person I recognize and like, or the smell I sense when I walk into the bakery is pleasant, or the voice I hear is my spouse).

Time

Time is the broadest and most inclusive level of organization within the developmental system (Overton 2006). Time (historical change) moderates the structure and function of all other levels of organization within the developmental system. Simply, things change. Individuals mature and grow older. Families evolve from a two-person structure to a structure with children in a household, to an “empty nest” when children grow up and leave home and start their own families. Social institutions and society change, as a function of natural events, for example, hurricanes, earthquakes, and of human-induced events, for example, wars, economic crises, or political upheavals. Accordingly, time has a different meaning at different levels of organization within the developmental system. For instance, as just illustrated, we may speak of individual time, generational time, and historical time.

Consciousness

This term is used within various facets of developmental science to refer to a facet of the

cognitive functioning of individuals. Consciousness refers to material in the current awareness of the person, that is, what the person is thinking, feeling, sensing, or perceiving at a given point of assessment.

Rationality/Reason

These terms are also used within various facets of developmental science to refer to facets of the cognitive functioning of individuals. For instance, rationality may be used to refer to functioning that reflects the person's adherence to logic, established facts, social conventions for appropriate conduct, or even accepted beliefs. Reason may at times be used synonymously with rationality or, alternatively, as a cognitive attribute involved in problem solving.

Mystery

Mystery is not a term typically used within developmental science. When it is employed, it may be a rhetorical device to dramatize the as yet unknown bases of a particular phenomenon or to point out that there remain many unanswered questions about the explanation of an observed facet of human development.

Relevant Themes

As an area of science that views religion and spirituality as essential foci of scholarship – given their status as potentially two species-defining characteristics of human functioning – developmental scientists would seek to elucidate the role of these characteristics within the relational developmental system. As a consequence, research seeking to study religiosity and/or spirituality would be framed within the following complex, multipart question: What physiological and psychological characteristics of individuals (ranging from the inner-biological, through the cognitive and affective, to the behavioral), in relation to what features of the multilevel context of development (ranging from the social relationship level through the family, community, cultural, natural, and

designed physical ecological to the historical), among individuals of what age, sex, race, religious affiliation, ethnic, national, etc. characteristics, impact what facets of religiosity and/or spirituality and, in turn, result in what impacts of religiosity and spirituality on the subsequent development of the individual and on the structure and/or function of his or her context?

Description

The sociology of deviance and social control is a subdiscipline of sociology that is also informed by concepts and theories from social psychology and social constructionism (Adler and Adler 2011). Social constructionism is a transdisciplinary approach to the study of social phenomenon that sees the social world, including social deviance, as an emergent outcome of routine practices of social interaction. The sociology of deviance and social control, which primarily emerged in the 1960s, examines the ways that human social interaction identifies some of society's members' behavior as: (1) different, (2) significant, and (3) negative, in its effect on other members (Henry 2009). It identifies people who experience others' behavior as offensive, the ways that they act to ban the behavior, and the forms of social control that they bring to bear on the perceived offensive behaviors, and on those committing such behavior. These control groups include "moral entrepreneurs" who reflect or generate

public support via the mass media to create rules or laws that ban or criminalize behaviors they find offensive (Becker 1963/1966; Cohen 1972/1980; Goode and Ben-Yehuda 1994), and also includes the formal and informal control mechanisms, such as ostracism and shaming; the process of labeling those designated as "outsiders"; and the construction of stigmatized categories of deviants (Goffman 1963/1986; Schur 1980). The sociology of deviance also examines the behaviors, both individual and collective, of those designated deviant, relative to others seen as "normal," whether this deviance is acquired (e.g., physical disability) or achieved (e.g., substance abuse). It examines deviant social organization and subcultures, their interactions with nondeviants, their private and sometimes secret lives, and the effects of the labeling and stigmatizing process, as well as the ways they can recover from the moral condemnation and exclusion embodied in the stigmatizing process (Henry 2009; Schur 1980).

Recent Developments

Recent developments in studies of deviance include: (1) debate over whether the field of social deviance is still relevant (Hendershott 2002; Henry 2009); (2) a more sophisticated understanding of moral panics and the stigmatization process (Goode and Ben-Yehuda 1994); (3) the positive ways shaming of behavior, rather than shaming people, can be used to effectively reintegrate those who have deviated, back into society (Henry 2009); (4) a shift from studying deviance committed by society's powerless, captured in the phrase "nuts, sluts and perverts," to studying deviance by society's powerful elites and corporations; and, (5) the emergence of a field of studies in positive deviance (PD) emanating from nutrition and health studies, and later, business and organizational change. This seeks uncommon solutions to recurrent economic, social, and community problems from within the range of behavior and practices that are successful and operative on the margins of

conventional practices (Henry 2009). A clear implication of the positive deviance model is that rather than exercise social control, its advocates seek to include this form of deviant behavior into the mainstream.

Theoretical Context

The sociology of deviance and social control has been predominantly set within the interpretationalist or hermeneutic tradition in sociology. While there are positivistic studies within the field, its major research, and the studies published in its major journal, *Deviant Behavior*, use qualitative methods, including ethnography, interview, and case study, to gather data on their subjects. Insofar as those methods are systematically organized, and meet the standards for qualitative research, then the field can be described as a social science in the same way that cultural anthropology is a social science. The field does not self-identify as a religion, although positivist critics might hold, especially in the case of radical social constructionists and some labeling theorists, that their ontological belief that social reality is a coproduction achieved through social interaction with no intrinsic reality beyond humans acting toward the named entities as though they were real, places it closer to religion where that involves a self-referential value system, than science. That it also adopts a cultural relativist stance in relation to difference and subcultures rather than a committed value position, also moves it closer to those religions that tolerate diversity, rather than those that adopt an absolutist stance (but see Hendershott 2002).

The sociology of deviance and social control is distinct within sociology in dealing with the inverse of the main discipline's concern, which is the problem of social order: the institutions and social processes that constitute a collective society or community. The sociology of deviance and social control addresses how mainstream or powerful groups within society deal with those whose behavior exists on its margins, the functional or dysfunctional role these behaviors, individuals

and groups play, and their perceived threat to social order, and what to do about both deviants and deviance.

It is also unusual to have a subdiscipline largely dominated by one theoretical framework, social interactionism/social constructionism (Adler and Adler 2011; Henry 2009), although some sociologists of deviance have introduced multiple disciplinary perspectives in an attempt to broaden theoretical explanation within the field (Pfohl 1994) which brings it closer to a criminological approach.

Relationship to Science and Religion

The sociology of deviance and social control intersects with science and religion through its studies of the process of moral identity and social control. Indeed, historically each of the three criteria, established for determining what counts as deviance, have been justified on moral grounds, in terms of the extent that a behavior constitutes "sin" and, in the extreme, that are embodied in law as "crime." These dimensions are: (1) extent and seriousness of the harm caused, (2) degree of consensus about whether the behavior is offensive, and (3) severity of society's responses.

Deviance as sin preceded the view that deviance was no more than negatively judged difference. The moral control of sinfulness is captured in Kai Erikson's classic book *Wayward Puritans* about the Salem witchcraft trials in seventeenth-century Massachusetts. As Pfohl has argued, this demonic perspective reveals that the control of deviance is a battle between good and evil, over "who gets to name the good and control the bad," and "deviance is, and always has been, a moral battle in which the winners are declared saints and the losers, sinners" (Pfohl 1994).

Significance

The major sources of insight for the field are the fact that two of its landmark texts, Kai Erikson's *Wayward Puritans* (Erikson 1966) and Howard

Becker's *Outsiders* (Becker 1963/1966), are among the best selling sociology texts of all time, with between 100,000 and 150,000 copies sold up to 1997. Erving Goffman's *Stigma* has also become required reading for anyone practicing in the field of mental health.

The self-fulfilling prophecy, is the essential idea of labeling theory describing the social process of creating career deviance from minor deviance, or as Edwin Lemert described it, creating secondary deviance from primary deviance. This has become embedded in popular discourse from education to criminology and criminal justice, and is a major reason justifying segregating juvenile offenders from adults in the criminal justice system, as well as for diverting juvenile offenders into alternatives to institutionalization. Indeed, in the broadest approach to the field, those theories that explain the causes of deviance are substantially the same as those that explain the causes of crime, albeit at different points in the lifecourse (Pfohl 1994).

Ethics of Sociologists of Deviance

The American Sociological Society's *Code of Ethics* governs the behavior of sociologists of deviance and social control and this Code also contains its key values. These include five core principles (elaborated in full at <http://www.asanet.org/about/ethics.cfm>): (1) maintain the highest level of professional competence; (2) maximize ethical integrity by acting in ways to avoid jeopardizing personal or others' welfare, and avoid making false, misleading or deceptive statements; (3) adhere to the highest scientific and professional standards and accept responsibility for work and ethical behavior; (4) respect all people's rights, dignity, and diversity, while striving to eliminate bias, intolerance, and any form of discrimination, and acknowledge the rights of others to hold values, attitudes, and opinions that differ from your own; and (5) act with social responsibility in order to contribute to the public good. Specific ethical issues affecting the sociologists of deviance relate to the source of its research material.

Assumptions About Core Concepts

The position taken by sociologists of deviance and social control on core concepts varies depending upon the theoretical position adopted by the sociologist, particularly their ontological position. The interactionist/social constructionist position is predominant in the field and it has a particular interpretation of these core concepts. It divides nature/world into a physical and social order. Following sociological phenomenologist Alfred Schutz, it takes the physical/natural world as a reality that can be directly experienced and conceptualized by scientists in a "first-order" sense. In contrast, the social world is already pre-constituted by other social beings and so the social scientists is only able to make "second-order" constructs based on reinterpreting the first-order constructs of those in that social world.

Human beings are in the world as physical and social entities. Their social being is as a human agent who can act individually and collectively, but the intersection of the individual and social world is such that individual agency is more or less colored by social agency, as in social psychologist George Herbert Mead's intersection of the "I" and the "Me," that reflects the collective social other's view of that individual.

Human agents are energized to act, but are not fully free to act outside of the discursive social frameworks that serve as the medium for their interaction and expression. Life is a series of interactive experiences of the physical world, and of the socially meaningful world of others, mediated by the social and institutional forms that humans have pre-constituted.

Death is a socially meaningful transition point in which individual human agencies cease to contribute to the ongoing reproduction of the existing social order that will continue to be reproduced by those still living.

Reality is the concreteness of the physical world, mediated by the social, and the socially constructed world of meaning that humans continuously create and reproduce, sometimes as closely replicated forms of that which already exists, sometimes as variations and transformation of that emergent reality.

Knowledge is the accumulation of concepts, theories, and research applications about the physical and social worlds at a variety of levels, from formal and organized down to informal and spontaneous; from academically organized, objective knowledge to experiential, subjective knowledge. In its organized form, what counts as knowledge and how it relates to the worlds that produce it, varies by historical era and stage of societal development. In the present era, organized knowledge is divided into disciplinary fields and subdisciplinary specialties, gathered by different methods, depending upon the discipline. In contrast, interdisciplinary “integrative” sociologists of deviance avoid the disciplinary division by applying methods to integrate knowledge across disciplines to produce a unity of holistic knowledge deemed to provide a more comprehensive understanding of the phenomenon.

Truth is seen as an artifact of the process and methods used to gather data and, in the radical social constructionist interpretation, is a variety of truth claims, no more, no less. From this perspective there is no underlying reality than the different interpretations of what is perceived as the constituted reality.

Perception comprises the ways that ongoing constituted reality is seen and acted toward as though it were real, so contributing to its ongoing constitution.

Time is the relationship in space through which social reality is recurrently constituted.

Consciousness is self-awareness and social awareness of our role as human agents in the ongoing production of what appears to be real.

Rationality/reason is a particular form of thinking about the world, born of a historical era associated with the Enlightenment, that is used to discriminate between other ways of thinking that are deemed irrational or unreasoned, in a similar way that disciplines are used to police what counts as acceptable and unacceptable knowledge to the academy.

Mystery is the state in which we suspend our conviction for the subject/topic at hand, that is, we question that we know or can know how or why events, processes, or outcomes happen,

assuming as we do, that such knowledge is possible or meaningful, other than the meaning that we attribute to it.

Finally, an additional critical issue facing sociology of deviance and social control is how the divisions between knowledge from science and religion can be transcended to produce a more holistic understanding of social phenomenon, without excluding knowledge on the basis that it is outside our present realm of disciplinary valued knowledge. The attempt to produce a common ground of knowledge, which does not marginalize some knowledge in favor of other knowledge, is a major challenge because it applies the sociology of deviance and social control to the structure of normal knowledge and the ways we seek to control deviant knowledge. At best, it takes a conscious reflexive stance toward its own field of knowledge production.

Dhamma/Dharma

Ven. Agganyani
German Vinaya Sangha Association (DBO) and
Centre for Buddhist Studies (CBS), Myanmar,
Bruckmuehl, Germany

Dhamma (Pāli) or *Dharma* (Sanskrit) in singular and generally denotes the Teaching of the Buddha, the truth or natural law he discovered, used for liberation, and taught.

Dhammā or *dharmā* in plural – according to context – usually point to phenomena, things, experiences, factors of existence, conditions, realities.

The conditioned phenomena (*saṅkhata dhammā*) have three characteristics:

1. Impermanence (*anicca*): They are impermanent and transitory phenomena arising and immediately vanishing totally again.
2. Suffering (*dukkha*): Through their transience, instability and liability to suffering, they all have the nature of *dukkha*, that is, they are unsatisfactory, deficient, or insufficient.
3. Non-self (*anatta*): They are void of an “I” or any permanent entity which could be called I, ego, self, or soul. The third characteristic applies to *Nibbāna*, the unconditioned *dhamma*, too.

Dhammā are ultimate realities (*paramattha dhammā*), the qualities of which are always the same, never change, while the *dhammā* themselves exist only momentarily. These realities, physical or mental, are exactly what one can experience directly with one of the six senses (including the mind). The observed object as well as the observing mind (subject) is transient and egoless. Only void phenomena happen and void processes run.

The *dhammā* are taught in greatest detail in the *Abhidhamma*, and they can be experienced, penetrated, and intuitively known by insight meditation (*vipassanā*), which has the power to transform and liberate the mind.

Dialectic

Eduardo Maura

Facultad de Filosofía, Universidad Complutense de Madrid (Spain), Madrid, Spain

Essential to the Western philosophical tradition, but not absent from Eastern philosophies, the dialectical method was founded by Plato and referred to philosophical implications of dialogue. Critical Theory deploys the term in its modern sense. These are basically the Hegelian view which, as Hegel himself has put it, declares that the purpose of dialectics is “to study things in their own being and movement and thus to demonstrate the finitude of the partial categories of understanding,” and the Marxist view.

For Marx, dialectics is the framework for development and home for the diagnosis of capitalist contradictions. What critical theorists do is to correct and to suggest different paths and philosophical uses of the term. Questioning traditional dialectics is precisely a major issue for them. In general terms, dialectics entail huge attention to contradictions, tensions, and interrelations between different aspects of materiality, nature, society, and the process of thinking itself.

Direct Perception

Harry Heft
Department of Psychology, Denison University,
Granville, OH, USA

The claim that perceiving is a process of keeping “in touch with” properties of the environment without the mediation of non-perceiving processes, such as memory. Experience of the environment is immediate, rather than being grounded in a mental construction existing apart from the environment. Things are experienced, rather having an experience of things. It

stands in contrast to the dualistic, post-Cartesian view that perception is always mediated (enriched) by stored mental representations either built up through prior experiences or in place innately.

Discernment

Carolyn M. Aldwin and Michael R. Levenson
Program in Human Development & Family
Sciences, Oregon State University, Corvallis,
OR, USA

Discernment refers to the quality of being able to comprehend what may be obscure. In the context of religious coping, it is a practice involving meditation, self-reflection, and consultation with others through which individuals seek to determine the Divine intention for the individual in a particular, usually stressful, situation. It involves trying to discern what the correct course of action is, as well as what personal characteristics individuals need to work on in order to apply the correct course of action and to remove barriers in their relationship with the Divine.

Divine Action

Christ event; Conservation; Creation; Divine government; General divine action; Miracle; Providence; Purpose; Special divine action

Description

The notion of divine action (DA) is central to theistic belief, especially to the Christian tradition, which will be the focus of this entry. The God of both Testaments is continually acting in the world to further His salvific purposes. In the primitive Church, the view of an idle God was considered a form of atheism. In contrast, the modern age has strongly attacked the idea of DA. Together with a fundamental theological reticence about the notion of an acting God and its anthropomorphic connotations, two main reasons for such a critical stance are the problem of evil and the claim that DA conflicts with the success of scientific explanations (see Tracy 1994, 1–4). In order to assess the pertinence of these objections we need to recall some important distinctions.

First of all, in spite of being semantically close, DA and providence are not synonyms. The concept of providence exceeds the concept of DA in claiming a certain degree of divine foreknowledge and planning. DA is usually differentiated into general or ordinary divine action (GDA) and special or particular divine action (SDA). GDAs are “actions of God that

pertain to the whole of creation universally and simultaneously,” while SDAs “pertain to a particular time and place in creation as distinct from another” (Saunders 2002, 21). GDA has to do with what Christian tradition calls creation and conservation of the world, provided conservation is not reduced to sustaining creatures in being, but includes habilitating them to exert their natural powers as well. SDA, on the other hand, relates to the traditional concept of divine government of the world, and its particularity can be either a result of subjective interpretation or an objective feature of that action. In the latter instance, the risk of conflict with scientific explanations becomes greatest (see Gwynne 1996, 119–226).

Objective SDA can be conceived both functionally and causally. In the first case, the event which is labeled as SDA differs from other events only by its special role in fulfilling God’s purposes, while in the second case particularity is due to a different causal history which does not result alone from the laws and processes of nature, that is, to the fact that God acts directly within world’s history to create the conditions for the occurrence of that particular event. (Functional and causal objective SDAs are almost equivalent to indirect and direct objective SDA, respectively.) We still have to make one more distinction, namely, between interventionist and noninterventionist objective SDA. Interventionist SDA implies disruption of the laws and processes of nature, that is, the classical concept of miracle. Noninterventionist SDA upholds the integrity of natural laws and processes, either taking place through them or, if they are supposed to be necessary but not sufficient causes of what is happening, complementing them in some way.

Given these distinctions, we are now prepared to briefly review the most important current types of theories of DA. A privileged site for assessing theoretical efforts to conceptualize DA is the six volumes of the project “Scientific Perspectives on Divine Action,” jointly run by the Vatican Observatory and the Center for Theology and the Natural Sciences (Berkeley, USA) from 1990 to 2008 (see Russell et al. 1993–2008).

The mainline participants in it underscore the relevance of SDA for a proper understanding of the Christian God. This is, however, a disputed thesis, as several theological positions exist (e.g., that of M. Wiles and G. Kaufman) that argue for the suitability of subsuming SDA within GDA. According to this, God relates to the world and history as a whole, not to particular situations. This cannot be equated with deism, since it affirms a continuous relation, not restricted to the temporal beginning of the world. Such a proposal must be seen as a response to the challenges that modern reason poses to the concept of DA: to do without SDA is an attempt to respect the alleged self-sufficiency of naturalistic explanations and exempt God from responsibility for evil.

The VO/CTNS project highlights two features of SDA. To do justice both to the Christian religious experience and to the integrity of natural sciences, it must be objective and noninterventionist. Let us look at what is thereby excluded. Subjective SDA is espoused by theological schools influenced by Bultmann's existential and demythologizing thought, but also by non-realist theologians such as D. Cupitt. Interventionist theologians are those who advocate a Humean concept of miracle, affirming that God may occasionally override the laws of nature to obtain particular aims. This position exacerbates the theological problem of suffering, as it presents a somewhat arbitrary God who corrects Himself. One of its foremost proponents is V. White. There are other ways of understanding miracles which are not interventionist; for example, assuming that the laws of science do not offer an exhaustive account of nature and conceiving miracles as law-transcending, instead of law-violating events.

When it comes to a more precise definition of noninterventionist objective SDA, there are two main approaches: one that stresses the role of metaphysics and the other that opts for direct dialogue with the natural sciences. Metaphysics is paramount both for neo-thomistic Catholic theology (e.g., W. Stoeger and D. Edwards) and process theology (e.g., I. Barbour and J. Haught). Neo-thomists build upon a basic distinction between God as the primary cause of all events

and creatural processes and beings as secondary causes through which God achieves His purposes. There is, therefore, cooperation between God and all actions of finite creatures. Process theologians admit SDA in all events as well, but do not underline God's transcendence as distinctly as neo-thomists do. Every actual occasion is influenced by God's "subjective lure," but also by efficient causality from the past and by the innate creativity of the occasion itself. Here we have an instance of direct SDA, while the neo-thomistic view subscribes to indirect SDA. But both positions are compatible with a causal order wholly regulated by natural laws (not all of which are known or even knowable by science); in other words, they do not need gaps in the causal order.

There are three main ways of approaching SDA in dialogue with concrete scientific theories. The first one, advocated by A. Peacocke and partly by Ph. Clayton, takes theories of complexity and emergence as its starting point. Upper levels of nature influence lower levels insofar as they impose boundary conditions on them. God is pantheistically conceived of as the whole which envelops the world, that is, as the world's environment, and exerts constraints on the behavior of its parts. This whole-part causation is also compatible with a deterministic view of reality. The other two strategies employ, on the contrary, particular gaps in the causal order and assume that noninterventionist objective SDA is only possible if reality is truly indeterministic. J. Polkinghorne, regarding chaos theory not only as epistemologically, but also ontologically indeterministic, makes use of some of its mathematical features to propose that God could guide the course of nature through input of information instead of energy. Finally, R.J. Russell, N. Murphy, Th. Tracy, and G. Ellis explore the possibility of locating SDA at the quantum level, concretely at the so-called collapse of the wave function, availing themselves of the stochastic character of the quantum world, which they construe indeterministically in the sense of the Copenhagen interpretation. In a nutshell: Quantum events are always underdetermined, and God resolves such an underdetermination, either in all or only in certain instances.

All these proposals have originated a fascinating debate, starting with the questioning of the notion of divine action itself. W. Wildman and W. Drees, for example, favor the so-called ground-of-being theologies, which try to do without this concept. Anyway, two crucial issues that remain open are of philosophical nature, namely, how to develop a broad enough concept of causation and elucidate the character of natural laws, whether they are descriptive or regulative. Furthermore, to guarantee DA not being located in only one level of reality is a permanent challenge. This requires, among other things, that DA in the providential guide of creation be adequately related to DA in individual human life and the history of salvation. Divine and human actions have, moreover, important structural analogies (for these questions regarding DA and human freedom, see Tracy 1994, 77–145). Another significant theological issue concerns the distinction between GDA and SDA itself. They cannot be separated from each other. We tend to see SDA as coming on top of GDA, but it is perfectly possible to conceive GDA as being always accomplished through SDAs. *Creatio ex nihilo* alone cannot be the template of all DAs; as a matter of fact, God's action in the Christ event must serve as the guiding criterion (see Edwards 2010, 25–33).

Life, death, and resurrection of Jesus are, from a Christian perspective, the most decisive of God's acts for us. That is where we get a glimpse of the real nature of the God who acts, where we learn about His unconditional love and unswerving fidelity to us. The image of a God who respects the integrity of His creation and is neither interventionist nor arbitrary removes many misunderstandings about suffering, the experience of a God who always stays by our side and nourishes the hope that evil will one day definitively be overcome (Bernhardt 1999, 462–466; Edwards 2010, 15–33, 143–150).

In any case, we can never intend to determine the “causal joint” between God and the world, to spell out how God acts; that is something we cannot know. Any theology of DA should recognize this fact and remain humble (Edwards 2010, 63).

[Creatio continua](#); [Creatio ex nihilo](#); [God as
semper Creator](#)

By all accounts, the starting point for a Christian doctrine of creation is in the Hebrew Scriptures, with the principal focus on the Genesis account. Although these verses are open to multiple interpretations, their articulation produced a twofold conviction: First, the universe had a temporal beginning, and second, in the beginning, God created all that is *ex nihilo*, (out of nothing). Over time, the doctrine of ► *creatio ex nihilo* came to represent both a theological and a metaphysical principle. Theologically, the doctrine of ► *creatio ex nihilo* preserved the unique eternity and sovereignty of God. Metaphysically, it ruled out the possibility that matter was a fundamental, primary, and eternal principle. Nonetheless, the tendency to identify the broader notion of creation solely with the singular divine act of ► *creatio ex nihilo* has, according to theologian William Carroll, resulted in a “fundamental confusion...about what creation is.” Focusing on the metaphysical and theological concepts, rather than on the particular act, the concept of creation “affirms that all that is, in whatever way or ways it is, depends upon God as cause” (Carroll 2010).

Scientist-theologian Arthur Peacocke echoed this understanding of creation as a relation of ontological dependence and cosmic contingency and asserted that “the postulate of God as Creator of all-that-is...is a postulate about a perennial or ‘eternal’...relation between God and the world”(Peacocke 1986, 95). In this relation, God is seen, not only as original creator of the cosmos, but also as its faithful sustainer and preserver. To model this perennial relation, Peacocke utilized a *Trinitarian panentheistic paradigm*. Within this model, God as the ground of cosmic being subsumes, permeates, and yet exceeds the being of the universe, which is dependent and contingent on the creative Being of God.

In contrast to the stasis implied in the notion of God’s sustaining and preserving the cosmos, however, evolutionary cosmology and biology continued to discover evidence of dynamism in the cosmos. Research indicated that cosmic creativity has been ongoing since the origin of the universe and has exercised such creativity in and through the very stuff of the material world.

Because of these scientific understandings, the theological notion of ► *creatio ex nihilo* as traditionally interpreted represented an inadequate conception of the creative relation of God to the cosmos. Although ► *creatio ex nihilo* could preserve the transcendent differentiation of God from the universe and the dependence and contingency of the universe on God, it could not accommodate the scientific understanding of the ongoing creativity of the cosmos in new and emergent forms. Hence, static conceptions of God’s differentiated relation to the cosmos, such as those of origination and preservation, had to be augmented and nuanced by a notion of dynamic interaction between God and world. Buttressed by the findings of the natural and physical sciences, many theologians have acknowledged that *creatio ex nihilo* must be supplemented in order to attribute this continuous creativity to God as Creator.

Theologically, the dynamic creativity between God as Creator and the cosmos as creation has been termed ► *creatio continua*. It arises from the understanding that the stuff of the world has an inbuilt creativity that makes the process of creation ongoing and incessant. Moreover, if God is understood as Creator and if the process of creation has been ongoing throughout cosmic history, into the present and the cosmic future, then the ceaseless creative processes revealed by the physical and biological sciences must be interpreted as the creative activity of God’s very Self exercised “in, with, and under the very processes of the natural world from the ‘hot, big, bang’ to humanity” (Peacocke 1986, 95–6). God is neither conceived as a separate or wholly transcendent creator dwelling in serene detachment from the cosmos, nor as a “God-of-the-gaps” who creates in sporadic or interventionist ways. God is Continuous Creator, directly involved in the continuing processes of the cosmos in creative relation.

In the Trinitarian panentheistic paradigm, the universe is conceived as an open system in receptive relation with the very Being of God, which both surrounds and permeates the cosmos. Creativity in such a paradigm can be conceived either through top-down or whole-to-part causality

or through bottom-up or part-to-whole causality. As applied to the God-world relationship, both have been appropriated as means by which one could conceive of God's interaction with the world without violating the laws and regularities operative in the cosmos, that is, in a way that would not be deemed interventionist.

In the panentheistic model of whole-part or top-down causality, God is the "circumambient Reality in which the world persists and exists" (Peacocke 1993, 158). The world-as-a-whole is thus conceived as within God, who is present to the world both in its totality and to its component parts. In this model, God is seen as always and everywhere freely and autonomously interacting with the world through an input of information. God communicates Godself and God's purposes to the world-as-a-whole through an all-embracing and all-pervasive presence that is essentially self-communicating. This self-communication trickles through the levels of its parts to those capable of receiving this communication.

Observations of self-organization in open systems continuously undergoing change and growth in a state of disequilibrium give evidence that the "whole" external environment in which a system exists has a relation of effect on its component parts. Philosopher Donald Campbell (1974) applied the interpretation of downward causation to the process of natural selection in the formation of jaw structures of worker termites and ants. In his study of how higher cultural values downwardly influence immediate humanitarian traits, psychologist Roger Sperry (1983) demonstrated that whole-part influence also applied to the realm of the behavioral and social sciences.

Conversely, in the panentheistic model of bottom-up or part-to-whole causality, "the stuff and processes of the world as we know it are...an expression of God in his modality as Creator" (Peacocke 1989, 35). Arising from the understanding that the stuff of the world has an inbuilt creativity, part-to-whole causality suggests that if God is understood as Creator and if the process of creation has been ongoing throughout cosmic history, then the ceaseless creative processes revealed by the physical and biological sciences

must be interpreted as the creative activity of God's very Self. As continuous and immanent Creator in relation to the cosmos, exercising divine creativity "in, with, and under the very processes of the natural world from the 'hot, big, bang' to humanity" (Peacocke 1986, 95–6), the creative dynamism of the cosmos is *itself* God's creative action; the creative processes of the universe are manifestations of the Divine as continuous Creator. This perspective understands God as *semper Creator*, "creating now and continuously in and through the inherent, inbuilt creativity of the natural order – a creativity that is itself God in the process of creating" (Peacocke 1986, 95).

Biochemists such as Ilya Prigogine and Gregoire Nicolis have demonstrated the dynamics of part-to-whole causality. They identified fluctuations within certain living systems and organisms which produce changes in the structure of the organism or system. In their studies, they found a class of systems with what they called "dissipative structures." These structures enable organisms or systems to maintain themselves in a state of order, although far from equilibrium. They found that when fluctuations in a system are amplified to a particular frequency, the entire system undergoes structural change. It becomes a newly ordered state with the capacity to take in energy and matter from the outside to maintain its novel form. They reasoned that a similar process of order-through-fluctuation made the conditions for the initial emergence of living organisms, as well as for their ongoing development, highly probable (Prigogine and Nicolis 1971).

In this perspective of divine creativity, God as Creator accords cosmic processes the same value and reverence that God accords to human choices, with God's activity as Creator as ongoing in, with, and under the entire cosmic process. These cosmic processes include the operation of law, the indeterminacy of chance, the unpredictability of events at the quantum level, the continuity of life forms, and the emergence of novelty, just to name a few. This convergence of cosmic dynamics, what John Polkinghorne calls the elements of "free process"

(Polkinghorne 1989, 77), which he sees as akin to human free will, constitute “the means by which the universe explores its potentialities, human-kind exercises its will, and God interacts with...creation” (Polkinghorne 1989, 78). Because of the divine choice to create the cosmos in this way – in autonomy and freedom, through chance within law, and indeterminate in principle – the continuing creation of the cosmos and its creatures results in a coincidence of opposites. Free process and free will not only occasion the emergence of new life forms, but also the inevitably costly process of diminishment and death. They produce not only the kaleidoscopic fecundity that delights both creatures and Creator, but also the calamitous events of pain and suffering. They create not only serendipitous moments of joy and well-being, but also events that cause the destruction and extinction of cosmic and human life. Moreover, evolutionary theory contends that it was, in fact, the free process of self-creativity through chance and law in the cosmos that resulted in the emergence of free persons, humans who “are not the mere ‘plaything of the gods,’ or of God,” but who are sharers in the “costly process of bringing forth the new” (Peacocke 2001, 37).

Divine Motivation Theory

Linda Zagzebski
Department of Philosophy, University of
Oklahoma, Norman, OK, USA

Related Terms

[DMT](#)

Description

Divine Motivation Theory (DMT) is a form of theologically based moral theory proposed by Linda Zagzebski. The theory defines all moral properties of persons, acts, and outcomes of acts in terms of God’s motives. God’s motives are states such as love and compassion, states that

are motivating, and that are emotions or similar to emotions. She proposes that these states constitute the metaphysical and conceptual basis for moral value. Given traditional assumptions about the nature of God, the theory combines moral realism with divine noncognitivism.

According to DMT, persons and their qualities are good in so far as they are like God or imitate God in the relevant respect. Human motives are good in so far as they are like the divine motives as those motives would be expressed in finite and embodied beings. Human virtues are those traits that imitate God's virtues as they would be expressed by human beings in human circumstances. Outcomes get their moral value by their relation to good and bad motivations. For example, a state of affairs is a merciful one or a compassionate one or a just one because the divine motives that are constituents of mercy, compassion, and justice respectively aim at bringing them about. Acts get their moral value from the acts that would, would not, or might be done by a being who imitates God in the relevant circumstances. God's own goodness and the rightness of God's own acts follow immediately from the theory since God himself is the supreme standard of all moral value.

This theory is a special case of a general form of virtue theory that Zagzebski calls "motivation-based virtue theory." If we assume that what makes an ethical theory a virtue theory is that it gives virtue explanatory centrality, such a theory must explain how an understanding of the nature of virtue illuminates other important concepts of moral evaluation, such as the concepts of a right act, an obligatory act, a good consequence, a good motive, and human well-being. In virtue theories inspired by Aristotle, the concept of a virtue is more basic than concepts of act evaluation, but not more basic than the concept of *eudaimonia*, or well-being. In theories of this type, a virtue is either a quality that reliably leads to *eudaimonia*, or it is a quality that is partially constitutive of a life of *eudaimonia*. In contrast, Zagzebski's motivation-based virtue theory makes the foundation of the theory exemplars of goodness – persons whose exemplification of goodness is identified without dependence upon a judgment of the person's well-being or

any prior evaluative judgment. In particular, she proposes that these persons are identified through the emotion of admiration. When we investigate virtuous exemplars, we see that their psychologically most basic good-making feature is a good motivational structure: Emotions that fit their intentional objects and which can motivate the agent to act in certain ways for certain ends. A virtue is a good motive disposition with reliable success in reaching the end of the virtuous motive. Moral properties of acts, intentions, and consequences are defined in terms of good motives.

Divine Motivation Theory gives a theistic foundation to motivation-based virtue theory since it adds to the structure just described the claim that God is the supreme exemplar. The theory permits the identification of human exemplars in the same way they would be identified without the theological foundation, but it maintains that human exemplars are exemplary because of their relation to a supremely good God. The theory also has a plausible Christian version since traditional Christian doctrine holds that Jesus Christ is both God and the most perfect human exemplar. There can be versions of the theory for other religions as well since many religions recognize exemplars, for example, the Buddhist arahant, the Jewish tzaddik, the Confucian sage, and of course, there can be secular versions.

The way DMT defines moral rightness and wrongness is structurally parallel to a form of Divine Command theory, with the important difference that DMT identifies the property of rightness with divine motivations like love and compassion rather than with the divine will or divine commands. Zagzebski argues that this means that famous objections to Divine Command Theory (DCT) do not arise for DMT. One problem for DCT is that if morality is grounded in God's commands, and if God can command anything, then it looks as if God could command brutalizing the innocent, in which case brutalizing the innocent would have been morally right, a highly implausible consequence. In contrast, it is impossible that brutalizing the innocent is right on DMT as long as being loving is one of God's

essential motives. The right thing for humans to do is to act on motives that imitate the divine motives. Brutalizing the innocent cannot imitate the divine motives as long as (i) it is impossible for such an act to be an expression of a motive that is like the motives of God, and (ii) it is impossible for God to have different motives. Assumption (ii) follows from the assumption that God's motives are part of his nature.

DMT does not face the famous Euthyphro problem either. The problem for DCT is that God's commands are either based on a reason, in which case the reason is the ground of moral rightness, not God's commands, or else God's commands are arbitrary. This problem does not arise in DMT. Although a command needs a reason, a motive *is* a reason. The theory says that the right thing to do is to acquire motives like God's motives. These motives provide the agent with both a reason for an act and the impetus to perform the act. DCT is appealing because commands are directed toward specific acts, whereas motives are much more general. On the other hand, versions of DCT that interpret God as giving very specific commands to agents are not very plausible.

Divine Motivation Theory has another theoretical advantage over DCT. DCT is most naturally interpreted as an ethics of law, a divine deontological theory, wherein the content of the law is promulgated by divine commands. But God's own goodness and the rightness of God's own acts are not connected to divine commands since God does not give commands to himself. In contrast, DMT makes the features of the divine nature in virtue of which God is morally good in the foundation for the moral goodness of those same features in creatures. Both divine and human goodness are explained in terms of good motives, and the goodness of human motives is derived from the goodness of the divine motives. DMT, therefore, provides a unitary theory of evaluative properties, divine as well as human.

Divine Motivation Theory has theological advantages. One is that it has the capability of resolving putative problems of inconsistency among the divine attributes. For instance, there is a set of puzzles arising from the idea that God is

perfectly good, where perfect goodness entails that God cannot be evil or do anything morally wrong. One problem is that the inability to do wrong seems to imply that God is not significantly free, so perfect moral goodness appears to be incompatible with divine freedom. For the same reason, perfect goodness appears to be incompatible with omnipotence. These puzzles are resolved if the goodness of all of God's attributes derives from God's motives. Perfectly good power is the kind of power God is motivated to have; perfect freedom is the kind of freedom God is motivated to have; and so on. Perfection of all kinds derives from the motives of a perfectly good God, not by reference to an independent standard.

DMT also leads to a reformulation of the logical problem of evil. What happens in the world is *ipso facto* something that is compatible with the divine motives, and cannot be deemed evil, all things considered. The real problem, however, is that many things occur in our world that seem to be incompatible with the motives of a loving God, leaving aside the metaphysical issue of the ground of value. That means that the problem of evil is not actually about the concepts of good and evil and the apparent inconsistency between a good God and the existence of evil. It is about the apparent conflict between the motives of the deity that make him worthy of worship (love, concern, etc.) and the motives apparently exhibited in a suffering world.

Divine Motivation Theory makes God the ultimate standard of goodness as exemplar rather than as lawgiver or judge. Since it gives a central place to virtue, it could be called a divine virtue theory, and since it maintains that the basic component of a virtue is an emotion or an emotion-like state, it focuses attention on the qualities of God that lead to a personal relationship with the divine.

Dualism

Roger Trigg
Emeritus Professor of Philosophy, University of Warwick, Oxford, UK
Senior Research Fellow, Kellogg College, University of Oxford, Oxford, UK

Related Terms

[Mind-body](#); [Mind-body problem](#); [Mind-body relationship](#)

Dualism is a philosophical term with a long history. It is often associated with such major philosophers as Plato and, in the seventeenth century, Descartes. It is still a live philosophical position and subject to much dispute. Although some would see it as “antiscientific,” others would claim that our belief in dualism is itself deeply rooted in human nature. Basically, it holds

that there are two different ontological categories, or levels of existence. In this, it is opposed to monistic theories which assert that there is only one kind of entity. As such, although it is not an intrinsically religious position, it is one required by any religion which looks to a transcendental, or supernatural, reality, alongside the world of ordinary sense experience.

“► [Materialism](#)” would be an obvious example of a monistic theory, opposed to dualism, because it holds that only “matter” exists. Modern scientific difficulties in defining matter have led to the greater popularity of such terms as “► [physicalism](#)” and “► [naturalism](#),” both of which tend to tie what can exist to what can be within the grasp of science. Whether that means present-day science, future science, or even hypothetical science remains a difficulty. All, however, would agree that reality must be defined in scientific terms and that the idea of any reality which is in principle inaccessible to science must be discounted.

Defining reality, however, in terms of the capabilities of actual or possible science is to make the idea of reality very anthropocentric. A typical dualist view does not start with what we can know, but with the kinds of things that exist. Naturalists want to rule out anything “supernatural,” but the dichotomy between God, as Creator, and the created, physical world, would be a form of dualism. God’s reality would not be thought to be physical, or limited by the spatiotemporal framework in which science operates.

Other forms of dualism, however, have also been influential. They also normally distinguish between physical and some other form of reality. The best known is that between mind and body, or the self and the brain. It is alleged that our reality as persons is not constituted by our physical makeup. I am not my body. My body ages, but I, it may be thought, am the same person throughout all physical change, growth, and decay. A particular instance of this view would be the belief that death is not the end, that “I” can survive the dissolution of my body. Another instance is the experience of my own mental events and the strong feeling that they are not

the same as any bodily accompaniments, even of a neurophysiological kind. Pain is not just the firing of neurons, it will be maintained. It is a specific kind of sensation, and its felt quality can never be reduced to bodily events or forms of behavior. Not all unpleasant sensations are pains, and not all pains are unpleasant. (Trigg 1970) It may seem to follow that pain is defined by the way it subjectively feels. It may be associated with bodily and brain events of various kinds, but they must be understood as the cause of pain and not be identified with it. This means, however, that the true nature of pain eludes the grasp of science. Similar arguments are mounted in favor of other “qualia,” such as the way red looks. It is a mental event which cannot be defined in terms of anything else.

All this is to raise the venerable problem of consciousness, with which scientists make little headway. Attempts to explain it in scientific terms have not just proved difficult. There are allegations that they have to be self-refuting. Science is always a human practice, engaged in by scientists who use conscious processes of reasoning. The idea of science explaining consciousness inevitably implies that it is able to explain itself. If science can explain the working of consciousness, it can also explain why scientists see one thing as true and another false. Yet it can be argued that science cannot itself distinguish between good and bad reasons for belief. It can only explain why those beliefs were caused in the first place.

Dualism certainly challenges the naturalistic, and even deterministic, assumptions which can easily become part of the working methodology of science. It is itself a metaphysical thesis about the nature of reality and may well be seen by many to restrict the scope of science, perhaps in an illegitimate way. Dan Dennett, a leading contemporary philosopher and prominent atheist, accepts (Dennett 1991) that if “dualism” is the best we can do, then we cannot understand “human consciousness.” He had just remarked (Dennett 1991) that “given the way dualism wallows in mystery, accepting dualism is giving up.” In other words, dualism is incompatible with

a scientific stance. Yet that is itself to assume the metaphysical view that only what is within the reach of science can exist.

The word “mystery” is easily invoked in connection with dualism. Whenever the reality of two entities is specified, there is going to be a problem as to how they interact. This is a notorious problem for dualism, dating back to the work of Descartes, although insisting that the connection is understood in physical terms already begs the question against dualism. It is to assume that the only possible causal connections are those understood by science. One reply is that we all, each day, have personal experience of the way mental events control, or influence, our bodily processes and behavior. One attraction of the doctrine is that it allows interaction between mind and body. In other words, there is causation both ways, both upward, from the body to the mind, as when we suffer injury and suffer pain, and downward, when our conscious desires and decisions affect what we do. The very idea of “psychosomatic” illness points to ways in which our conscious states can even affect our health.

Modern cognitive science complicates the issue by drawing attention to the fact that we do naturally, as humans, tend to think in dualist terms, at least about the relation of the mind and body. As the anthropologist Emma Cohen points out (Cohen 2007), recent research in the area suggests we are “natural Cartesians.” In other words, not only do we think our minds – our thoughts, feelings, and sensations – are different from bodily processes. We find it easy to think of the separation of the mind and the body, as Descartes did. She shows how even the idea of minds migrating between bodies is easy for us to grasp. Most significantly, the strong belief in human societies of all kinds that a person survives the dissolution of the body seems natural for humans.

Philosophers such as Dennett tend to deride such “► folk psychology.” They may accept the reality, and ubiquity, of our common sense beliefs, but consider that they must be supplanted by the findings of science. Yet seeing human beings in a neo-Darwinian context, continuous with other animals, does not itself resolve the

issue of mind-body dualism, as it is an open question how far animals may have mental experiences which are caused by physical events, but are not necessarily identical with them. They may see colors for example.

Dualism is a central issue in questions concerning the relation of science and religion. The nature of the human personality is of major importance for any religious understanding, as is the question of the nature of reality. Dualism maintains that the human self is more than its body, and not necessarily to be identified with it. It is the locus of our identity and often identified with the “soul.” Those who wish to follow some modern science in refusing to accept “mysteries,” such as the nature of consciousness, are adopting an antidualist metaphysics. Yet in ruling out any division between body and mind, more than this is being claimed. If the only reality can be physical, however defined, this brings us on a collision course with another form of dualism, that between God and world. The same antimetaphysical arguments which dispense with human consciousness as a separate entity must also hold against a belief in a God who is separate from the spatiotemporal world (Taliaferro 1994).

In other words, some form of dualism is essential to traditional theism and also underpins many other forms of religious views, invoking spirits, and nonmaterial influences. In some ways, the idea of an immaterial “self” is a mirror image of God. Indeed, as it is claimed by monotheists that humans were made in God’s image, that is perhaps not surprising. Whether dualism is hostile to a scientific outlook, or even underpins the possibility of scientific rationality, remains a vexed question (For more on the brain and the mind see Trigg 2002).

[Duḥkha \(Sanskrit\)](#); [Suffering](#); [Unsatisfactoriness](#)

Description

The predicament of *dukkha* and the way to freedom from it are the chief motivation of the Buddhist soteriological enterprise. According to a dictum found in the early Buddhist discourses, what the Buddha teaches is simply the nature of *dukkha* and its cessation (Trenckner and Chalmers 1888–1896, I 140). While the existence of *dukkha* as a motivation for adopting a spiritual life appears to have been a common concept in ancient Indian thought, the Buddhist approach to this problem stands out for conceptualizing the human predicament of *dukkha* in terminology reminiscent of medical analysis, namely, by way of the four noble truths

(► [Truths, Four Noble](#)). From the perspective of the dialogue between science and religions, this is significant, since in this way Buddhism presents its perhaps most central teaching deliberately couched in medical terms.

The term *dukkha* is often translated as “suffering.” This translation does not adequately capture the range of meaning of the term and even runs the risk of giving a misleading impression. Hence, the meaning of the term needs further examination.

According to a statement made in the early Buddhist texts, *dukkha* covers whatever is felt (Feer [1884–1898](#), II 53). If on following the standard translation one were to render *dukkha* in such a context as “suffering,” this would result in the proposal that all felt experience is simply suffering. Such a conclusion would directly conflict with a standard analysis of felt experience in early Buddhist discourse, according to which feelings can be pleasant, painful, and neutral. These three types of feelings are mutually exclusive in the sense that at the time one has one type of feeling, one does not experience the other (Carpenter and Rhys Davids [1890–1911](#), II 66). According to another discourse, the above dictum regarding *dukkha* covering all that is felt has the impermanence of feelings in mind (Feer [1884–1898](#), IV 216). The changing nature of feelings, however, need not be experienced as “suffering.” While a change of pleasant feeling to its opposite could indeed result in suffering, a change of painful feelings to its opposite would rather be experienced as a relief (Trenckner and Chalmers [1888–1896](#), I 303).

This goes to show that all feelings are not necessarily “suffering”, nor is the changing nature of feeling invariably something that results in “suffering.” Yet, no type of feeling can provide lasting satisfaction, precisely because the nature of feelings is to be impermanent. Hence, a better way of translating *dukkha* would be as “unsatisfactory,” although perhaps the best solution is just to keep the original form of the term, thereby allowing for a sense that ranges from outright pain and

suffering to the unsatisfactoriness of pleasure, dependent on the context.

The problem with the translation “suffering” is not only that it does not capture the full compass of meaning of the term *dukkha*. This rendering also tends to give the misleading impression that the Buddhist teachings are predominantly concerned with the negative sides of existence and that Buddhism is an instance of pessimistic thought in ancient India.

This does not appear to be the case, however, since the importance of joy and happiness is repeatedly emphasized in the teachings of early Buddhism. A collection of Buddhist poetry has a whole chapter dedicated to the theme of happiness (von Hinüber and Norman [1994](#), Stanza 197–208), and joy is reckoned one of the so-called factors of awakening, thus being a necessary requisite for progress toward liberation.

This much can also be seen in the case of the four noble truths, the central mode of exposition on the significance of *dukkha*. The first noble truth defines *dukkha* and the second noble truth traces its arising to craving; thus, these two presentations are concerned with negative aspects. But then the third noble truth takes up the positive value of the cessation of *dukkha*, and the fourth noble truth delineates the equally positive notion of the practical path that leads to freedom from *dukkha*. This thus gives an overall rather balanced impression, instead of reflecting an excessive concern with the depressing sides of existence.

The nature of *dukkha*, according to the first noble truth, covers physical events such as disease and death, as well as the mental displeasure that can arise from being unable to satisfy one’s desires. Thus, the range of meaning of *dukkha* extends from barely noticeable dissatisfaction to outright suffering as inherent features of human existence. Another presentation distinguishes between three chief aspects of *dukkha*: related to the experience of outright pain, related to the state of being subject to conditions, and related to the fact that things invariably change

(Carpenter and Rhys Davids 1890–1911, III 216). The actual manifestation of *dukkha* could then be overwhelming or just trifling; moreover, *dukkha* might disappear quickly or last for a long time (Morris and Hardy 1885–1900, III 416).

According to the first noble truth, manifestations of *dukkha* can be summed up under the heading of the five aggregates affected by clinging. These five aggregates are considered in early Buddhism as the chief constituents of an individual, comprising bodily form, feeling, perception, volitional reactions, and consciousness. Thus, *dukkha* can in the final count be traced back to clinging to various aspects of oneself.

In other words, the actual experience of *dukkha* requires personal involvement in what is taking place by way of clinging, attachment, and craving. Such clinging, attachment, and craving are in the end simply a manifestation of ignorance. This is reflected in another central Buddhist doctrine related to the topic of *dukkha*, namely, dependent arising. According to this doctrine, the arising of *dukkha* hearkens back through a series of conditional links to the presence of ignorance. In turn, with the cessation of ignorance, craving and clinging cease, and therewith the cessation of *dukkha* is accomplished (► [Dependent Arising](#)). A fully awakened one, who has eradicated ignorance, has gone beyond being affected by *dukkha*, as even the experience of physical pain will not cause him or her any mental distress.

Dukkha is one of the three characteristics of existence recognized in Buddhist thought, together with impermanence and the absence of a self. According to a standard teaching, because all conditioned things are impermanent, they cannot yield lasting satisfaction – they are *dukkha*. Since they are *dukkha*, however, it is not reasonable to identify them as a self (► [Anattā](#)). Thus, from the perspective of the development of liberating insight in Buddhism, *dukkha* forms the transition point from an appreciation of impermanence to insight into the absence of a self. With insight fully developed,

then, the cessation of *dukkha* through the attainment of liberation is attained and future rebirth is therewith transcended.

Dukkha: Suffering

Ven. Agganyani

German Vinaya Sangha Association (DBO) and Centre for Buddhist Studies (CBS), Myanmar, Bruckmuehl, Germany

Dukkha (Pāli) or *duhkha* (Sanskrit), a key term and truth in Buddhism, is usually translated as suffering. According to the context, *dukkha* is either direct suffering, being liable to suffering, a bodily painful feeling, or unsatisfactoriness, deficiency, insufficiency.

The Buddha declared suffering in the first Noble Truth: “Birth is suffering, old age,

disease, death is suffering, to be united with unbeloved ones is suffering, to be dissociated from beloved ones is suffering, not to get what one wants is suffering, in short, the five aggregates of clinging are suffering.” (Dhammacakkappavattana-Sutta, Saṃyutta-Nikāya, S 56, 11) These types of suffering are evident, which all beings have to face; they are unavoidable. But the Buddha penetrated suffering and found its cause, which he taught in the second Noble Truth: Craving (*taṇhā*). The third Noble Truth declared the cessation of suffering by the complete end and liberation of craving. Finally, the fourth Noble Truth gives the practical way how to remove craving and be freed from suffering through following The Noble Eightfold Path.

Dukkha in the context of feeling (*vedanā*) denotes the bodily unpleasant or painful feeling. Altogether the Buddha taught five kinds of feelings, which should not be mixed up with emotions which are already reactions to the primary feelings or sensations. If only three feelings are mentioned, *dukkha* represents unpleasant bodily as well as mental feelings, that is, pain and unhappiness.

Dukkha is one of the three universal characteristics of existence. Here, and in the context of insight-meditation (*vipassanā*), *dukkha* is the unsatisfactory, imperfect, deficient, and insufficient quality of all formations or conditioned phenomena (*saṅkhāra*), and of all worldly experiences too. The intuitive insight into this characteristic leads to detachment, disenchantment, and turns the mind to the quest for *Nibbāna*, which alone does not have the quality of *dukkha*, but to the contrary, is highest bliss and true happiness. All phenomena have the intrinsic nature of *dukkha* according to the three types of *dukkha*:

1. *Dukkha-dukkha*: Some phenomena evidently are painful and suffering directly in themselves (such as headache, worry, anxiety, etc.).
2. *Vipārināma-dukkha*: All phenomena have the nature of “*anicca*” impermanence, so they

cannot satisfy permanently. Even happy feelings and desired emotions will change, dissolve, and cease. One cannot control them or make them permanent.

3. *Saṅkhāra-dukkha*: All phenomena are conditioned by some other phenomena, which themselves are impermanent and conditioned. A network of conditions has to work harmoniously together in order to produce one phenomenon as result. One has no power or cannot control the resulting phenomenon which arises and vanishes according to its own natural laws.

Penetrating to this truth of *dukkha* in insight meditation (*vipassanā*) for whatever conditioned object one’s mind grasps, as well as for the subject, one’s own mind, leads to disenchantment and finally to neither like nor dislike but equanimity (*upekkhā*) toward these conditioned objects, which is called *saṅkhār’upekkhā-nāṇa*, the knowledge of equanimity toward conditioned phenomena. This is the highest worldly insight a *vipassanā* meditator can achieve. After this, one is ready for the experience of *Nibbāna*, the unconditioned, which has none of the above-mentioned attributes of *dukkha*.

The contemplation of suffering (*dukkhānupassanā*) is one of the three main methods in insight meditation. It discards desire through craving. *Nibbāna* first appears through the desireless aspect and the practice leads to desireless emancipation (*appaṇihitā-vimokkha*) with concentration as gateway to liberation.

Dynamical System

Achim Stephan
Institute of Cognitive Science
University of Osnabrück, Osnabrück, Germany

A means of describing how one state develops into another state over the course of time. In engineering and mathematics, a dynamical system is a *deterministic* process in which a

function's value changes over time according to a rule that is defined in terms of the function's current value. Simple nonlinear dynamical systems and even piecewise linear systems can exhibit a completely unpredictable behavior, which might seem to be random. This unpredictable behavior has been called *chaos*.

Orthodox Christians

The Eastern Orthodox strand of Christian theology is strongly traditionalist, with the writings of the Fathers of the early centuries of the church – especially those of the Greek-speaking east – remaining the touchstone for theological authenticity. A major feature of this patristic background is an understanding of the created order that stresses the strong linkage between the concepts of creation and incarnation. In its patristic expression, this theological vision was inevitably expressed in terms of the scientific understanding of the late antique world, and this has proved problematical for some Orthodox Christians of the present day, for whom the secular thought of the last few centuries has sometimes seemed to be at odds with patristic

perspectives. However, the Fathers themselves – especially the Cappadocians – developed a sophisticated natural theology using the scientific insights of their time, and in principle a neo-patristic approach incorporating the sciences of our own time is seen as possible by many. Moreover, many of the best Orthodox theologians of the past century have, like Christos Yannaras (2004), explored issues of epistemology in a way that reflects the work of St. Gregory Palamas in the fourteenth century, and their insights arguably provide the basis for such a neo-patristic synthesis. If there is still a strong suspicion of modern science among some of those who see themselves as the Fathers' spiritual heirs, this suspicion is by no means universal.

Why, then, does this suspicion linger? Here part of the answer may lie in sociological factors. Many Orthodox lived until very recently in situations in which they were inevitably influenced by the need to react against the Marxist-Leninist version of atheism, with its supposed "scientific" basis, so that even after the downfall of that ideology in their countries some of them still tend, almost instinctively, to see science and atheism as having an intrinsic connection. In addition, at least some influential Orthodox in the West have developed a similar attitude for reasons that are susceptible to comparable analysis. Especially if reacting against the recent "liberalization" of many of the mainstream Western forms of Christianity, they too may tend to associate science with the ideologies of those they perceive to be the enemies or diluters of faith.

This suspicion of science among at least some Orthodox Christians should not, however, be equated with the attitude of “fundamentalist” Christians of the West. While the two groups are sometimes comparable in sociological terms, their theological views are often very different. For example, even though modern historical-critical study of scripture has had relatively little influence in Orthodox circles, scriptural exegesis in these circles is far from fundamentalist in the Western sense, in that it is strongly influenced by the way in which patristic authors often read the Old Testament scriptures using an allegorical rather than a literal mode of interpretation, and with a creative use of the science and philosophy of their time. This means, for example, that the creation accounts in Genesis are not usually seen by Orthodox Christians as expressing literal, “scientific” truths about the way in which the cosmos came into being. (Indeed, patristic writers such as St. Gregory of Nyssa quite explicitly set aside the literal meaning of these texts.) As a result of this patristic basis to their thought, it is not science and philosophy as such that are looked at with suspicion by some Orthodox Christians, but only what are perceived (rightly or wrongly) to be perverted forms of these disciplines. Neo-Darwinian insights in biology are, for example, still sometimes held to be incompatible with Orthodox faith, though advocates of these insights do seem to be becoming more numerous among upholders of that faith.

Given this complex background, it is hardly surprising that there is, as yet, no consensus about how to formulate a contemporary Orthodox response to the sciences in general and to neo-Darwinism in particular. Moreover, intellectual ferment in this area – characteristic of Western Christianity for several generations – has (with the notable exception of a number of theological appraisals of psychology) been effectively absent from Orthodox circles until relatively recently, and this again makes the wide spectrum of existing views within those circles more readily understandable.

At one end of the spectrum is the essentially antiscientific attitude of writers such as Seraphim Rose (2000) and Philip Sherrard (1992).

The former of these effectively defends a kind of fundamentalism in relation to the patristic literature. The latter – with major concerns about ecology and about the need for the revival of a “sacred cosmology” – fails to perceive any validity in the distinctions commonly made between technology and pure science and between science and scientism. For their supporters, anything in current Orthodox thinking which reflects the positive view of modern science that is characteristic of the mainstream of the Western dialogue between science and theology represents an unacceptable dilution of Orthodoxy.

At the other end of the spectrum lie writers such as Basarab Nicolescu and Christopher Knight. These, while insisting that Orthodox perspectives have an important role to play in the science-theology dialogue of the future, do not reject the Western dialogue of the last two or three generations, with its positive attitude to science and its view that scientific insights provide genuine insights into major theological themes. Nicolescu – who in his Romanian homeland has led the first major effort to develop a structured and widespread science-theology dialogue in a traditionally Orthodox country – has focused on essentially philosophical issues, taking bold and controversial strides to formulate a “transdisciplinary” approach that affects not only the science-theology dialogue but every area of human thought (Nicolescu 2002). Knight, in a rather different way, has focused on theological issues, arguing that one of the main resources that Orthodoxy can bring to the current dialogue is a “teleological-christological” understanding of created things, of a kind that he sees as a valid extrapolation from the thought of St. Maximus the Confessor. In an updated form that acknowledges current scientific insights, he argues, the traditional Orthodox understanding of the link between creation and incarnation can provide a new framework within which the legitimate questions enunciated by participants in the Western dialogue can be answered more satisfactorily than they have been when examined in a purely Western context (Knight 2007).

Between these extremes of the Orthodox spectrum lie writers who, while not rejecting science,

effectively deny the validity of the kind of dialogue between it and theology that has taken place among Western Christians over the last few generations. Among the exponents of this kind of position, few have direct experience of science or a deep understanding of it. A notable exception, however, is the cosmologist, Alexei Nesteruk, who perhaps presents the most scientifically informed argument of this intermediate kind. While affirming science as being a legitimate expression of the human spirit, he tends to bypass the questions that characterize the Western dialogue – about truth in science and theology, and about the consonance or dissonance between them – by interpreting both in terms of the philosophical approach known as phenomenology. Major themes in Orthodox theological thought can, he claims, be incorporated in this approach (Nesteruk 2008).

Given this wide spectrum of views, and the sociological framework within which they at present interact, the future of Orthodox theology in its response to the sciences of our time is hard to predict. Will sociological factors continue to affect the discussion that has now begun in earnest, so that what, in the short term, comes to be seen as the mainstream Orthodox position may reflect the effects of these factors rather than of a full appreciation of the resources that the Orthodox tradition has to offer? Or will the epistemological issues on which many contemporary Orthodox theologians have focused allow the development of a more subtle and creative response, which will have an impact not only in the Orthodox world but beyond? Activity in this area in the early twenty-first century – with several new initiatives based, like Nicolescu's, on a real understanding of the content of contemporary science – represents a hopeful sign that this latter outcome is the more probable one, at least in the longer term.

Description

► **Ecclesiology**, from Greek *ekklesia* (church) and *logos* (discourse), is the analytical and constructive study of the (self-) understanding of the Christian Church in its varieties of forms and practices.

The term ecclesiology has a double reference. It is the more or less coherent understanding of what is church held by a church, a movement, or a person. This understanding can be explicit or implicit. Ecclesiology is also an academic discipline studying these ecclesiologies.

As an academic discipline, ecclesiology originates in dogmatics and the need for a more specialized field of studies depending on a more focused development of the understanding of the church in theology at large during the nineteenth century. During the last part of the twentieth century, ecclesiology integrated theories from history, sociology, anthropology, and other disciplines in humanities and social sciences due to growing insights that the church could not be understood only by interpreting documents and theories but also needed to be understood from the perspective of science. This in turn led to an emerging integration of ecclesiology also in nontheological academic fields like political science, sociology, and history.

In universities and academic institutions, ecclesiology, partly depending on recent developments partly on history, is either an independent discipline or a subdiscipline, often related to dogmatics, social sciences, ecumenics, law, or history. As an academic discipline, ecclesiology differs worldwide in form and content among the institutions which include the discipline.

The church as an object of studies is a unique phenomenon in the world of religions and organizations, claiming to be itself divine revelation and by analogy the presence of Christ, the human-divine founder of the church. Historically, the church has decided about the biblical canon (at the end of the third century) and all dogmas (about the Holy Trinity, ► **Christology**); so basically, all information about the Christian faith is based on the church.

From the times of the early church, however, the church has been characterized by controversies and a constant striving to maintain or reestablish unity.

Self-identification

Science

Depending on language, the connotation of science differs also in relation to the self-understanding of ecclesiology.

Ecclesiology appeared as a part of the teaching in dogmatics during the late Middle Ages and remained so until it became a part of the university system during the twentieth century. It then became a part of systematic theology/dogmatics at the university where it partly served the traditional purpose of the constructive confessional theology of the churches and partly by means of church history emancipated itself from the teaching authority of the churches. As an academic discipline, ecclesiology during the twentieth century has combined the dogmatic and historical perspective with empirical studies and theories used in sociology, anthropology, political science, etc.

The use of ► **history** in ecclesiology is manifold. It originates in the insight that the church dogmatically is an historical phenomenon. Therefore, the dogmas on the church must be read in the historical context to be understood (Yves M.-J. Congar (1904–1995)). But history also presents constructs for ecclesiological analyses. If one, for example, researches the circumstances of the cheap production and distribution of Bibles during the last part of the nineteenth century and contextualizes it in the framework of the emergence of political liberalism and individualism, this is one of the most important ecclesiological changes in modernity.

► **Sociology** and ► **anthropology** offer ecclesiology tools for investigating what is church as a fellowship or assembly (*koinonia*, *ekklesia*). But ecclesiology integrates theories from social sciences with theories taking into account the theological presuppositions or postulates necessary to understand the claims of the church to be

a unique part of a given divine revelation, that is, the theological aspects. Ecclesiology is thus compared with sociology and anthropology, not an empirical science even if it takes into account and integrates them into ecclesiological studies because empirical data are a too narrow scope. Sociology goes together with theological interpretations like Christology and soteriology in ecclesiology. What sometimes is called empirical ecclesiology is used to create data for systematic theological analyses. The church is a political and historical reality that claims to be a divine revelation. It is at the same time ► [incarnational](#) and ► [eschatological](#). One of the problems when correlating ecclesiology to sociology, except for the German sociology of the church (Kirchensoziologie), is that its research object is religion at large which for ecclesiology is too vague and therefore sometimes irrelevant.

Constructively, social sciences and political science have played a decisive role in, for example, Latin American liberation ecclesiology, based on exploratory ecclesiological research. The same could be said about feminist ecclesiology and especially in relation to studies on power in the church. Not uncommon is the use of social sciences when developing middle-range theories for understanding church in a certain context.

The church is an organization, sometimes easily identified as a bureaucratic institution and in any society related the dominant administrative procedures and theories of administration for its administration of finances, buildings, personnel, etc. It is the same church which administer finances and sacraments. When the church today in its life integrates management theories, ideas of professionalism for its ministers, and introduces the concept of service in a manifold meaning, this, of course, affects the self-understanding of the church and is then an object for ecclesiological studies. If earlier in the history of the church it could be and still can be studied as a teaching institution with a magisterium and those who are taught by that teaching office, today it can be studied by means of categories like provider and consumer.

Cooperation between ecclesiology and ► [political science](#) and the use of ecclesiology and political science in each discipline is grounded in the fact that they are not possible to separate, for example, when studying Western constitutional thought, the idea of nation or kingdom, at least up to the nineteenth century. It was possible to distinguish between the political and the ecclesial worlds but not to separate them. Political science also is of importance for ecclesiology, for example, when studying the ecclesiology of a political party. There are studies in how communist parties in Eastern and Central Europe both made analyses of an ecclesiological character and presented coherent understandings of what is church that is ideologically motivated ecclesiologies.

Ecclesiology has to take into account the various anthropologies presented in the theological self-presentations made by the ecclesial traditions themselves. There is no fundamental and common view of the human being in the academic discipline itself.

The church is as a community a system of communication in word and deeds, which according to its own self-presentation expresses the unity between God and the believers and between the believers. To ecclesiology, this means that it must engage in ► [communication science](#) to understand what it implies and to have the possibility to theologically interpret the phenomenon (German “kommunikationstheoretische Ekklesiologie”).

Religion

The church is not a religion unless it by abstraction is converted into Christianity in the modern meaning of the word, an idea invented during the eighteenth century and developed by the phenomenologists of religions during the eighteenth and early nineteenth century. Thus, the study of the church cannot be understood as a religion and so not even the dogmas on the church. In some academic institutions, however, ecclesiological studies are founded on theories that are intimately related to specific confessional standpoints.

Characteristics

The distinctiveness of ecclesiology among the academic disciplines is a debated issue.

Ecclesiology is the theoretical interpretation of the self-understanding and self-realization of the church and how this has been understood and developed by churches, movements, and persons in theory and practice, in history, and in contemporaneity.

During the last century, ecclesiology less and less was confined to a perception of dogmatics as an isolated and of other disciplines than philosophy unaffected reflection on what is the true church. This is still to a certain extent true, but the church is nowadays commonly not understood as a generalized abstraction that is detached or possible to detach from its worship, institutions, or actual life.

Ecclesiology is not restricted to materials produced in the ecclesiastical domains. Also, for example, a state or a political party, as well as a novelist can produce ideas or systems of ideas about what church is or might be according to their opinion. Consequently, also, these can be subject to ecclesiological analyses.

Ecclesiology is organized differently at various academic institutions. In some, it is a discipline called ecclesiology or by a similar name; in others, it is either a subdiscipline in another discipline or combined with another discipline in the same department. Examples of combination are dogmatics, church history, ecumenics, canon law, and practical theology. Sometimes, individual scholars make research in ecclesiology in other disciplines, for example, sociology and political science.

The task of ecclesiology is to keep together the understanding of the church from various perspectives (dogmatic, social, cultural, and so on). The church as an object for studies is a complex and sometimes inconsistent phenomenon, and ecclesiology must necessarily make distinctions but cannot separate the various elements in ecclesiology as it is an object of the study. Such a separation would lead to a fragmentation of the object (church). In ecclesiology, different

aspects and elements are integrated or put in relation to each other in such a way that the church, whatever that means, retains its integrity.

In recent years, ecclesiology has bridged the traditional divide between empirical and theological analyses because of a renewed interest in the cultural and social expressions of the church but also new possibilities to add new knowledge to traditional dogmatic or systematic theological problems by means of theories presented by disciplines directed toward empirical studies.

Relevance to Science and Religion

Ecclesiology has until present times not explicitly on a broad basis engaged in the scholarly area called “science and religion.” Its increasing engagement in other disciplines and the incorporation of ecclesiology in, for example, social sciences will, however, demand such an engagement. Also, the fact that ecclesiology constructively has used, for example, models in physics as well as insights from biology in its hermeneutical assets will contribute to this.

From the 1960s, the idea of model used in social and natural science, particularly in physics, has influenced ecclesiology (Avery Dulles 1918–2008). It is interesting to observe that ecclesiology when being most theological in character, pursuing various sorts of analogical imaginations, is related to natural sciences. In ecclesiology, thus, the relation to natural sciences, is established in the framework of systematizing biblical images of “church,” not in the context of science, for example, political science or sociology. In physics, it is observed by ecclesiologists, the use of model has a clear similarity with the understanding of analogy not least from the perspective of neoscholastic theology. Models in ecclesiology are used in two ways: as explanatory models, which functions as means for synthesizing, and exploratory as means to achieve new perspectives and new knowledge.

During the 1930s and 1940s, there was a debate among especially Roman Catholic

theologians whether the analogy of the church as the Body of Christ was excessively influenced by concepts used in biology. Anyhow, explanatory models in biology has been used to understand what, since the nineteenth century, was called the organological perspective on the church presented by more or less botanical images in the New Testament (vine tree, body, etc.) that describes change without dissolving the identity.

In constructive ecclesiology, the idea of corporate person, corporate personality, or extended personality has been developed with help of development psychology both as a hermeneutical tool and an analytical instrument. This is understood as a phenomenon common to the ecclesiology of Israel and the church. One could say that psychology has offered hermeneutical tools for ecclesiology. It is of importance here to remind us about the relation between the individual person and the corporate, communal entity that is the church. In classical ecclesiology, an individual gets his or her identity by belonging to the fellowship called church.

Sources of Authority

Fundamentally, ecclesiology is an analytical and a critical and constructive reflection on a postulated divine revelation, as this is expressed in the Christian Church and interpreted in manifold ways through ideas and practices. This is the basis for the academic and scientific work of various schools in the field of research.

In ecclesiology, the productivity of the theories to which the individual scholar adhere is presenting the authoritative frame of the discipline.

Ethical Principles

The ethical principles in the field of ecclesiology are depending on the requirements held by the individual discipline that is included in the actual research made, for example, sociology or research in archives.

Key Values

The key values in ecclesiology are developments of (new) theories and presentation of new knowledge about the church, acquired by the larger academia, the churches, and the society.

Conceptualization

Nature/World

The object of ecclesiology is not relational, for example, church and world but the study of the church per se. However, studies of nature and world are included in, for example, sacramental theology, integral in some ecclesiology. Recently, ecclesiology has also been engaged in studies in ecology.

Human Being

An ecclesiological question is raised when there is a discussion about the identity of an ecclesial tradition, and it is about the relation between an individual person and the corporate person, that is, the church. If aspects of identity is brought in from psychology and applied on an organization and in this case an ecclesologically founded corporate person, the question about the real image and the subjective image of the subject occurs, the problem with an external as well internal regenerated identity as well. This is in ecclesiology possible to approach by means of tools presented in social sciences, including anthropology and psychology; the interaction between the person and social structures are studied and the person cannot be detached from collective processes of experience.

Anthropology at large has influences on the ecclesiology held by the churches. One example is the difference between Baptist and Lutheran view on the child which finds expressions in different views on baptism and thereby the organization of the church. This is thus a field of ecclesiological studies.

Life and Death

Theologically, the church claims on the basis of the Bible to be an eschatological phenomenon,

that is, transcending the borders of heaven and earth. In Christian anthropology, the idea of the beginning of the individual person's life has shifted according to the understandings in biology during history and that is applicable also to death. In ecclesiological structures, birth, dying and death have been interpreted by means of various rites and practices, for example, baptism and funeral ceremonies. For academic ecclesiology this implies a multidisciplinary approach, considering dominating patterns of understanding presented by history of ideas and social and natural sciences.

Reality

In ecclesiology, the ideas of reality differ depending on epistemological assumptions held by the individual scholar.

Knowledge

Knowledge produced in ecclesiology is possible to evaluate in the academic fields of theology and in accordance with the theories and methods applied in specific research done.

Truth

The churches' ecclesiologies generally present absolute and universal truth claims. Ecclesiology as an academic discipline does not make such claims. Thus, truth in ecclesiology depends on the researcher's philosophical position and the theories used.

Time

Theologically, the church builds on the idea of incarnation, that God has become a human person in Christ and that the church is the living Body of Christ. Therefore, history is an essential element in many ecclesiological investigations studying continuity and change of the church.

Rationality/Reason

Rationality in the field of ecclesiology as an academic discipline seems from the perspective of constructive ecclesiology to be system immanent in the meaning that it depends on the philosophical preconditions for a certain theory or cluster of theories. One thing seems, however, to be in

common, namely, that as the object itself transcends in its totality empirical verification, so ecclesiology as a field of research is not confined to empirical data and that those data must be interpreted in such a way that the theories and methods are intelligible in the larger academia.

Mystery

The church is from the Biblical presentations of it and onward offered by categories of mystery. This affects ecclesiology in two ways: It has in the research to consider the claims of the church to be a mystery also when it is studying its organizational or political character, and it motivates studies of the idea of mystery itself and how it is used.

Ecological Optics

Harry Heft

Department of Psychology, Denison University,
Granville, OH, USA

Analysis of the ways in which radiant light interacts with surfaces of the environment, and, in turn, the manner in which the resulting reflected light is structured by those surfaces. The array of reflected light serves as potential information for perceiving, and as such creates the possibility for direct perception of environmental layout. Formulated by James Gibson in his ecological approach to perception-action.

Description

► [Ecological psychology](#) is a term that has been applied by three different psychologists to their distinct, independent theoretical approaches and associated research programs: the perceptual psychologist *James J. Gibson (1903–1979)*, the child/social psychologist *Roger G. Barker (1903–1990)*, and the child psychologist, *Urie Bronfenbrenner (1917–2005)*. Roughly contemporaries, all three developed their individual approaches over the second half of the twentieth century. Because of their different research interests and approaches, there was little overlap, or

even cross citing, among them. Still, the three share some common historical antecedents. The thematic thread linking all of them, however, is a careful and systematic consideration of the environmental context for psychological processes. All concur that the environmental context for the development of perception, thought, and action has not been given adequate attention in ways most suitable for psychological considerations.

Overall, an ecological approach in psychology takes as its basic phenomena the ongoing, reciprocal processes of a dynamic environment-organism system. Psychological processes are viewed as operations of organisms in transaction with their *econiche*. *Econiche* refers to that portion of the environment that is functionally significant for a particular species. The *econiche* is specified relative to the living habits of an animal or a group of animals. Moreover, environment-organism systems are seen as being embedded in a nested hierarchy of natural systems. Consequently, in addition to its emphasis on reciprocal environment-organism relations operating within a psychological level of analysis, an ecological approach calls attention to between-level influences, especially those stemming from the higher-order systems (e.g., sociocultural processes) within which psychological processes are embedded.

Let us briefly consider an overview of each of these distinct “ecological psychologies”:

James Gibson’s Ecological Psychology

James Gibson’s ecological psychology takes as its starting point the dynamic environment-animal relationship, and its primary concern is the act of perceiving (Gibson 1979). A unique characteristic of the ecological approach is its intention to provide the theoretical grounds for a philosophy of *direct realism* – the position that individuals perceive the environment directly (i.e., without the mediation of nonperceiving processes) (Heft 2001; Reed 1988, 1996). The claim of ► [direct perception](#) (sometimes called pejoratively, naive realism) stands in contrast to the

view dominating much of post-Cartesian thought that perceiving the environment is always mediated by stored mental representations (*indirect realism*). An epistemological consequence of this latter position is the assumption that what the individual perceives is a mental construction of the environment, rather than the environment itself. The threat of Humean skepticism, and even solipsism, ever looms over this position.

In contrast to the standard position that perception is the result of a linear sequence of causal events – from imposition of physical stimulation on stationary receptors to subsequent stimulus “processing” along a neural stream to the brain – Gibson proposed that the senses be “considered as perceptual systems” of an *active, exploring perceiver* (Gibson 1966). Actions by the individual play a critical role in revealing structure (information) specific to environmental features and events. To illustrate, it is far easier to identify an object through active touch (i.e., manipulation by means of the tactile perceptual system) rather than by passively holding the object. In both cases, sensory receptors are stimulated, and yet successful identification of the object is far more likely in the former case. Likewise, perceiving objects through vision is facilitated by actions of the visual perceptual system (e.g., movements of the head and body), in comparison to a fixed, stationary view. Why is it that actions contribute to detection of stimulus information? Activities of perceptual systems help to reveal what is invariant (i.e., the relations that do not change in the context of change) in the stimulus array. Such invariant structures specify stable and persisting features of the environment. (An account of how such structure is available in reflected light is offered through Gibson’s development of ► [ecological optics](#) (Reed 1988; Gibson 1966; Reed and Jones 1982). The detection or “pickup” of structure specific to objects and events by means of perceptual systems makes possible the *direct (unmediated) perception* of environmental layout.

An especially significant concept formulated in Gibson’s later writings is ► [affordances](#) (Gibson 1979). Gibson proposed that *what* is perceived through the pickup of information is

the affordances of the environment. The term “affordance” refers to meaningful properties of the environment taken with reference to an individual. For example, a surface affords “sitting on” if it is approximately at knee height and if it appears to be able to support one’s weight. Consequently, what affords “sitting on” has particular properties taken with reference to an individual. As such, affordances are neither solely properties of the environment nor properties of the perceiver, but they are relational properties within an environment-perceiver system. Critically, then, the concept of affordance transcends the standard Cartesian objective-subjective dichotomy and is characteristic of a relational ontology. This concept has drawn much attention in recent years because it raises the possibility that *meaning* originates in dynamic perceiver-environment *relationships*, rather than being solely a subjective quality in isolated minds. This way of thinking opens up the prospect that meaning is a property of the environment-individual systems and that, ultimately, it can be located in a public, shared domain of experience (Reed 1996).

Much of Gibson’s ecological psychology is anchored in the experimental research tradition. Ongoing empirical research has deepened our understanding of the nature of affordances and of the information supporting locomotion. Moreover, it has been fertile ground for research in movement science as well as perceptual and motor development, the latter domain of inquiry initiated by Eleanor J. Gibson (1910–2002) (Gibson and Pick 2000). Gibsonian ecological psychology is currently a thriving area of research and inquiry. The International Society for Ecological Psychology (www.trincoll.edu/depts/ecopsyc/isepp/journal.html) meets regularly and publishes a journal (“Ecological Psychology”) as well as a book series.

Roger G. Barker’s Ecological Psychology

Roger G. Barker’s ecological psychology (later called by him “eco-behavioral science”) started with his realization that even though psychologists knew a great deal about how children

behave within laboratory conditions, they knew little more than laypersons about children's behavior patterns and experience in daily life. In response to this shortcoming, Barker followed the path set by naturalists in the biological sciences and established a field research station, in this case, in a small town, that provided "easy access to phenomena of the science, unaltered by the selection and preparation that occur in laboratories." In due course, Barker and his colleagues developed empirical methods for observing and recording the activities of children in everyday circumstances (Barker 1968).

Their extensive observations revealed an order or pattern in individuals' actions that could not be adequately accounted for solely by considering the environment as it operates at the level of the individual child. Instead, Barker found it necessary to identify higher-order structures that emerge from the actions of two or more individuals in concert with environmental objects and other features ("milieu"). He called these dynamic structures ► **behavior settings** (Heft 2001; Schoggen 1989). Joint, coordinated actions by individuals generate the dynamic structure of the behavior setting, and reciprocally, those actions are constrained by that structure in the course of generating it. To take a simple example, a chess game between two individuals is a dynamic structure constituted by their joint action in some milieu. Their participation in, and hence creation of, the game simultaneously constrains their actions. Barker began to see communities as being comprised of behavior settings that their inhabitants participate in to varying degrees of involvement. Observations such as this led him to conclude that the best predictor of individuals' actions is knowing "where they are" (i.e., in which behavior setting are they currently participating) rather than knowing their "intrapsychic" traits (e.g., personality).

One important insight that grows out of behavior setting research is the psychological implications of "*levels of staffing*." "Optimal staffing" occurs when the requisite number of individuals needed to fill the essential roles of a setting is present. In conditions of "understaffed" settings (less than the requisite number present),

individuals must be intensively engaged in the setting, often taking on more than one role, in order to preserve the setting's operational integrity. Understaffed settings, then, often challenge its participants, and if the degree of understaffing is not too extreme, they are challenged in psychologically beneficial ways. Conversely, overstaffing results in some individuals in the setting being superfluous to its operations, and hence marginalized. This analysis of the psychological impact of "staffing" applies directly to organizational and institutional settings, such as schools and workplaces.

With the closing of the field station, and the passing or retirement of the first generation of eco-behavioral psychologists, work along these lines has been steadily declining. The demise of this research program is also partially attributable to the very demanding, long-term nature of the research, which is at odds with the institutional practices within the discipline of psychology. Unfortunately, with the passage of time, this significant work is being remembered by a dwindling number of psychologists.

Urie Bronfenbrenner's Ecological Approach to Human Development

Urie Bronfenbrenner's ecological approach to human development (later called the bioecological approach) primarily focuses on the social contexts for interpersonal processes that have an impact on the developing child. Bronfenbrenner pointed out that after decades of child development research, psychologists know very little about the environmental influences operating at many levels of society that affect child development. As a consequence, he lamented, child developmental psychologists have little to offer to those working in the realm of public policy that bears on child welfare. Bronfenbrenner's emphasis on the policy implications of human development research distinguishes his work from that of the others considered here.

The most distinctive feature of his approach is a model of the developing child as being

embedded in a series of nested systems of influence, conceptualized as a set of concentric spheres of dynamic, mutually interacting processes (Bronfenbrenner 1978). The most immediate reality from the perspective of the developing child is the *microsystem*. This system is the primary developmental context, consisting of the child, the available environmental resources, and typically another person (e.g., a parent). It is necessary to recognize that the parent is but one of a number of relations with which an individual child operates at a microsystem level. Other microsystems include the relationship of the child with a sibling, a relative, a peer, or a teacher. Because of the coexistence of multiple microsystems, the relationships between microsystems require close consideration. For example, the character of interpersonal processes in a microsystem that includes a sibling may have an influence on dynamics of the child–parent microsystem and so on. Bronfenbrenner refers to these relations between microsystems as *mesosystems*. Unlike microsystems where children are participants, ► *exosystems* are interpersonal and institutional conditions that can affect the child indirectly even though he/she is not a participant in them. For example, the parent’s experience in the workplace can affect the character of the parent–child microsystem even though the child is not a part of the former. Other instances of exosystems that may indirectly affect child development are the decisions by school boards on educational/curricular matters, by neighborhood planning boards concerning play space, and by legislators on children’s rights. Bronfenbrenner also identifies what he calls *macrosystem* processes, by which he means the culture’s value system(s), political ideology, etc. These macrosystem factors have a pervasive influence on all of the systems nested within it. Later additions to his model are the *chronosystem* that refers to the temporal patterning of life events at each of these levels, as well as the biological resources that play a role in developmental processes.

Bronfenbrenner’s ecological psychology conceptually cuts across numerous traditional disciplinary boundaries, including sociology,

economics, political science, and anthropology. This interdisciplinary breadth is both its strength and its challenge when it comes to formulating a comprehensive, contextually sensitive framework for the analysis of human development as well as for intervention. Bronfenbrenner did not develop a sharply defined research program and often drew on existing research and data resources. Still the overall impact of his approach continues to be influential among researchers broadly interested in the contexts for human development.

Self-Identification

Science

Ecological psychology, in all of three of its variations, identifies itself as a science. Ultimately, the validity of its claims and concepts rests on empirical evidence. Most of the work in the Gibsonian tradition is based on experimental research, the Barker “school” followed along more naturalistic and descriptive rather than experimental lines, and the evidentiary base of Bronfenbrenner’s approach draws on a combination of “natural experiments” (comparison of existing conditions for development) and demographic data sources. A significant challenge all three face is to develop research techniques and ways of analysis that capture the dynamic, environment-organism phenomena at the center of their respective programs.

Moreover, each of them in their own way is interdisciplinary, at least within the sciences, connecting with empirical and theoretical work in other domains of scientific inquiry. Recent developments in Gibsonian ecological psychology have been exploring linkages with the physics of complex systems, particularly concerning motor performance and coordination, and with dynamic systems research in motor and cognitive development. Barker recognized that with the discovery of behavior settings as extra-individual environmental structures, his focus shifted from exclusively that of the individual to collective, ecological structures. He understood that he was operating at the boundaries of traditional

psychology and the social sciences, and for that reason, he began to call his research approach “eco-behavioral” science. Bronfenbrenner’s program, as we have seen, cuts across the traditional boundaries of the biological, psychological, and social sciences.

Characteristics

In spite of differences among these separate programs, each in its own way attempts to elucidate the properties of the environment that are significant from a psychological perspective. Barker’s and Bronfenbrenner’s ecological psychologies draw attention to environmental properties that, respectively, either have gone largely unnoticed before (i.e., behaviors settings) or that rarely figure into psychological analysis of child development (i.e., mesosystems, etc.). Gibson’s ecological psychology is more far-reaching than the others, however, in its call for a radical transformation in how environment-organism relations are conceptualized.

Following in the footsteps of the American pragmatist tradition, Gibson’s ecological psychology explicitly rejects dualistic approaches to psychological phenomena (see above). The environment and organism are relational concepts, each implying the other. Environment-organism is a dynamic system, neither facet of the system is possible without the other. To illustrate by way of a biological process, respiration is not an organism property that operates in itself, but rather it is a function of an environment-organism system (in the absence of oxygen, there is no respiration). Reciprocally, oxygen as one of numerous chemical constituents of the biosphere is biologically significant because of its function in organisms’ respiration and metabolism. Psychological processes and the environment are to be conceptualized in a likewise manner.

At the level of psychological functioning, what animals perceive and act on are the environment’s affordances (see above), and reciprocally, animals regularly modify the environment to fashion affordances that support life activities (e.g., spider webs, beaver dams,

human shelters) – processes that have been called in recent years niche construction. From this perspective of environment-organism systems, then, features of the environment are meaningful and value-laden taken with reference to an animal. As a result, meaning is not solely a property that resides in the mind considered in isolation, but rather it is *grounded* within an environment-perception/action system. Approaching meaning from the starting point of perception/action establishes the basis for viewing knowledge as being fundamentally *embodied*. The last decade has witnessed a surge of research on embodied knowing within cognitive science stemming from this insight.

Relevance to Science and Religion

None of the variants of ecological psychology have direct relevance to “science and religion” as a scholarly area. That said, Gibson’s ecological psychology, with its starting point being the environment-organism systems and its identification of meaning as a relational property of that system, would view both science and religion as frameworks for human activity operating within such systems. Barker’s ecological psychology considers religious institutions (e.g., houses of worship) as behavior settings that emerge from collective action and thought (belief) and, reciprocally, create contexts/constraints that make religious practices possible. Bronfenbrenner would most likely view the stances toward living offered by science and by religion as macrosystem influences on human development.

Sources of Authority

The authority for ecological psychology, like any scientific endeavor, rests on empirical, pragmatic criteria: ideas that prove to be useful for ongoing processes of inquiry and understanding are to be valued. At the same time, these ideas remain open to scrutiny, to revision, and even to rejection when other empirically grounded, substantive ideas are formulated that challenge them.

As far as historical sources, James Gibson's ecological approach to perception rests in part on the *radical empiricist philosophy of William James* which claims that immediate conscious experience includes objects *and* their relations (Heft 2001). Traditional empiricist views have it that "relations" are not immediately perceived – a position that Hume demonstrated has devastating consequences for an empiricist epistemology. Gibson's mentor was Edwin B. Holt, one of James's students and the earliest proponent of molar (nonreductive) behaviorism. Gibson was also deeply influenced by the phenomenology of Gestalt psychology, especially by Kurt Koffka, and by the dynamic field theory developed by Kurt Lewin, which took as central the claim ($B = f(P, E)$) – behavior is a function of joint person and environment influences. Likewise, the works of both Roger Barker and Urie Bronfenbrenner were inspired by the work of Kurt Lewin, who was their mentor.

Ethical Principles

As a science, ecological psychology in its variations adheres to the ethical practices of the sciences involving human research. Participants' anonymity is protected, and whenever possible, participants' informed consent is obtained. Observational research can often make it difficult to meet the latter criterion; however, in Barker's ecological psychology research, the individuals who were being observed were aware of the researchers' presence and were informed about the aims of the investigation. Moreover, as in all the sciences, ethical practices in scholarship, such as properly attributing work and faithful, accurate reporting of evidence, are strictly maintained.

Key Values

Ecological psychology is principally an area of empirical inquiry. It seeks to gain understanding and insight into the human condition by drawing on empirical information and on the formulation

of evidence-based concepts and theory. To the extent that this empirical information can be utilized to improve the quality of human life, as well as the quality of the biosphere, it is especially valued. While any science goes beyond its data to develop models and theories, which in turn facilitate the prediction of future possibilities, those predictions must be grounded in existing evidence. Ultimately, predictions must be rejected and theoretical commitments critically evaluated in the absence of confirmatory data.

Conceptualization

(The following comments are intended to reflect the perspective of Gibson's ecological psychology only. No doubt there would be much agreement among all three psychologists on the following, but still some subtle differences may exist on certain matters. I will not explore these possible differences here.)

Nature/World

Nature refers to all that is from the standpoint of the sciences. Within that all-encompassing domain, ecological psychology distinguishes between the environment and the world. The environment is that which exists in relation to living organisms (Gibson 1979). The world is all there is independent of considerations of living organisms. The physical sciences have developed quite sophisticated descriptions and models of the world defined as such.

Environment and organisms exist relative to each other and, indeed, are facets of a common, dynamic system. The environment refers to those aspects of the natural world that are significant because of their value for specific organisms. Reciprocally, in many instances, some properties of the environment result from organisms operating in the natural world (e.g., from the production of oxygen by plants to the building of burrows and nests, human dwellings, and settlements).

From the standpoint of science, then, there are no multiple worlds (e.g., the physical world, the natural world, the social world) – but one, the

natural, some parts of which are especially significant for some types of scientific inquiry and some types for others, such as environments for biological and psychological functions.

Human Being

Human beings are members of the species *Homo sapiens sapiens*, and current evidence indicates that the species evolved roughly 200,000 to 150,000 years ago. The biological similarities between them and other primate species are considerable, but the relatively small biological differences that do exist have resulted in enormous psychological and behavioral differences over time. Human beings are highly social with possibilities for cooperative processes unmatched by other primate species. The comparative ease with which humans can offer and receive instruction and can develop symbolic systems of thought, requiring a long period of dependence on others, has allowed for extended collaborative, planning processes and, critically, has made possible the accumulation of know-how across generations. Thus, although many primates show evidence of protocultural processes in terms of cooperative action and instruction (e.g., in tool use), humans alone have developed the possibilities for processes (e.g., systematic pedagogy, making symbolic records) that allow for the preservation of collective gains of successive generations. Further, symbolic processes make possible different frameworks of thought (e.g., religion, mythology) that provide a basis for collective action as well as for individuals' efforts toward finding meaning in their existence. Possibilities for *culture* and *cultural evolution* rest on these combined foundations.

Life and Death

The origin of life is a topic outside of the purview of ecological psychology. That all living systems eventually die is a fact of biological processes.

Reality

What constitutes reality varies depending on one's purposes (life sciences, physical sciences, social sciences, religion). This is not a relativism, however, but rather a pluralism because it is

accepted that certain conceptualizations may operate well for some purposes but not others, and vice versa. What is reality for living things is their immediate perceptual reality – their perceived, living circumstances. The reality that is relevant to ecological psychology is the perceived environment taken with reference to active organisms, that is, affordances. Likewise, a mathematical or a cosmological framework is to be valued in the context of their associated conceptual or symbolic systems.

How might one differentiate between “perceptual” reality and “conceptual” reality? Conceptual systems are intellectual abstractions from immediate experience. As such, they can be – and have been – replaced by other conceptual systems. The reality of environment-organism systems is present in ongoing immediate perceptual experience, and facets of it must endure if environment-organism systems are to remain viable. Extinction occurs when the reality of the environment necessary for a species' existence ceases to be.

Knowledge/Truth

Ecological psychology's stance on knowledge and truth follows the pattern established by pragmatist philosophers. *Knowledge* consists of those acquired practices (habits) and ideas that successfully serve as means to the individual's ends. However, individuals always operate within social contexts; therefore in the long run, these individual practices and ideas must be in concert with social norms and collective goals. Moreover, all ends of praxis, both individualistic and collective, are established over the course of development within social contexts.

Truth is knowledge that has successfully stood the test of time, including assessment by individuals within a social group who care to evaluate it. Although some outcomes may satisfy a narrow set of goals for a segment of the social group in the short run, truth is warranted only over the long run and, in principle, from the perspectives of all social group members. Although long held *truths* (traditions) should not be discarded casually or without due consideration, neither should they go

unchallenged or unrevised when they clash with reliable, empirical evidence, and when they no longer serve human interests and what humans take to be the interest of the biosphere.

Perception

Perception is the major concern of Gibson's ecological psychology (Gibson 1966, 1979; Reed and Jones 1982). In this regard, it follows the tradition of Aristotelian and British empiricist thought positing that knowing stems from perceptual experience. However, unlike most empiricist approaches, ecological psychology rejects the position that perception is a linear chain of causal events, from the stimulation of sensory receptors, which produces simple sensations (or sense data), to the mental construction of a percept based on those sensations, supplemented by memory. Instead, sensation and perception are treated as separable processes, and perception (but not sensation) is the means by which perceivers stay in touch with meaningful features of the environment (e.g., affordances – see above). Perceiving involves the detection of relational structure in the environment – structural relations specify their environmental sources – and structure is not carried in sensations (Gibson 1966). Moreover, because structure is most readily detected with respect to what remains constant in a changing pattern of stimulation, actions by the perceiver (i.e., functioning of the perceptual systems) play a critical role in perceiving. In an information-rich environment, memory is not needed to supplement perceiving processes, because perceiving – like all processes of a living organism – is an ongoing and continuously transforming process of a dynamic environment-organism system. Change is always ongoing. Structures that are detected by way of perceiving processes also serve as the foundation for higher level nonperceptual processes (e.g., imagining, remembering). Finally, ecological psychology takes the standard dichotomy of nativist-empiricist sources of knowledge to be a false choice based on dualistic thinking that distinguishes world and mind (see above). Perceiving is function of an environment-organism system, and perceptual information is constituted within this system.

Time

What is experienced is *change* due to environmental events (e.g., day-night cycle, seasonal conditions, growth and decay, inanimate and animate motion) and organismic action (e.g., self-produced locomotion, exploration, production) (Gibson 1979). Time is an intellectual abstraction based on events. Abstract systems of measuring time have been developed by humans to provide a common framework for ordering interpersonal affairs, and these systems are overlaid on the ongoing changes that are found in immediate experience.

Consciousness

Consciousness is a term with a wide range of meanings within psychology. Ecological psychology, to date, has been primarily concerned with consciousness qua awareness accompanying perception and action. For example, to perceive one affordance of the environment as opposed to some other is to be aware of the former. That is, awareness is not superadded to perceiving; rather to perceive is to be aware of some properties of the environment. In addition, perceiving the environment is accompanied by a coperceiving of the self. There is an awareness that it is “I” that is perceiving, as evidenced by the fact that, e.g., some alterable vantage point (rather than some other) has been adopted; that there is a self-referential locus of control for self-movement; and that parts of my body are enduring features of my visual field. This evidence points to an empirical, *embodied* “I” as opposed to an intellectualized “I.”

Rationality/Reason

Ecological psychology is concerned primarily with perception-action processes. For this reason, it has not addressed reasoning processes in living systems. That said, it has vigorously opposed the view that perception and action are a reason-like processes (e.g., that they are mediated/based on inferences, hypotheses, or “programs”). As explained above, ecological psychology provides the groundwork for considering perceiving through action to be a direct and unmediated process of engaging the environment.

Mystery

Science is driven by the experience of wonder when confronting natural phenomena. Within the bounds of science, wonder does not have a transcendent significance. Although the experience of “uncertainty” does not fully capture this experience, it is a part of it. Some of the experience of uncertainty may be resolved with greater understanding, but owing to the complexity of natural processes, and perhaps due to factors intrinsic to natural processes themselves, uncertainty is ever-present. With regard to perceiving, more specifically, as the individual explores the environment, new information comes into view and prospective (inherently uncertain) information appears on the forward edge of the awareness accompanying perception-action (Gibson 1979).

Relevant Themes

The ecological approach to perceiving provides theoretical and empirical grounds for a direct realist epistemology. Perceiving (perception-action) is a process of detecting publically accessible information that is specific to objects and events at various levels of complexity. The array of potential information available to be perceived is essentially limitless, and at any particular moment in time, individuals selectively detect some portion of this array owing to their prior history and current intentions. With opportunities for further individual exploration and perceptual learning, perceiving is an ongoing process of detecting new information, which both broadens and deepens the individual’s awareness of what is there to be perceived (Gibson and Pick 2000). And because perceptual information is publically accessible, the prospect is always open for individuals who may be selectively aware of different informational structures, even conflicting structures, to come to be aware of what the other perceives. Ecological psychology, then, is an epistemology of both direct realism and pluralism, and unlike post-Cartesian views that gesture in the direction of solipsism, by taking percepts to

be products of processes occurring in so many isolated minds, ecological psychology offers an epistemology of hope (Reed 1996).

Related Terms

[Environment](#); [Qur'an](#)

Islam is a religion that was born in the desert, and as such the first Muslims seem to have had a keen sense of the fragile balance that existed in the harsh ecosystem that made their lives possible. This awareness is abundantly reflected in the Qur'an, which contains many references to water and other vital natural resources and lays down clear guidelines for their conservation and equitable distribution.

The Islamic legal tradition, devised from the eighth to tenth centuries on the basis of the Qur'an and hadiths (reports about the words and deeds of the Prophet Muhammad), spells out in detail the divinely prescribed parameters for the use of natural resources, including water, soil, air, plants, and animals. As in the Qur'an, conservation and fair distribution are emphasized. Moreover, like everything in creation, resources are seen foremost as belonging not to humans but to Allah, for whom humans are to hold nature in trust (*amāna*).

Humans and Nature in the Qur'an

The Qur'an presents natural phenomena as signs (*āyāt*) pointing to the existence of God (16:66, 41:53, 51:20–1, 88:17–20). The value of nature is therefore primarily symbolic. Scientific inquiry which aims to understand the workings of the universe thus constitutes, for Muslims, a sacred quest. Nature is perfectly proportioned and without any flaws (67:3), a reflection of the qualities of its creator. It has a divinely ordained purpose (3:191, 21:16, 38:27) and is neither random nor meaningless. The “environment” is

nothing less than God himself, since, according to the Qur'an, “whithersoever you turn there is the presence of God” (2:115).

Within the hierarchy of creation, the Qur'an accords humans a special status that of God's *khalifa* (2:30, 6:165), which has been generally understood by Muslims to mean “vice-regent,” thus one of stewardship or trust (*amānat*). Recently Idris has criticized this as a later interpretation, however, arguing that the original meaning of *khalifa* was “successor”; according to this view, humans are not the “deputies of God” but simply the “successors to Adam” (Idris 1990).

Nevertheless, the Qur'an states that “all that is in the earth” has been subjected (*sakhkhara*) to humans (22:65) and that “It is He who has created for you all things that are on earth” (2:29). Yet ultimately, it is God “in whose hands is the dominion of all things” (36:83; cf. 2:107, 24:42). And though humans are said to have been created “in the best of forms” (*fī aḥsanī taqwīm*), the Qur'an goes on to caution that “Assuredly the creation of the heavens and the earth is [a matter] greater than the creation of human beings: Yet most people understand not!” (40:57).

Humans are described in the Qur'an as being more like other beings than unlike them. All creation is said to worship God (22:18), even if their praise is not expressed in human language (17:44, 24:41–2). Nonhuman communities are said to be like human communities (6:38), and nonhuman animals are explicitly said to possess speech (27:16). Nonhuman animals are said to have received divine revelation, as when God instructs bees on how to make honeycombs and honey (16:68). The earth was created for the benefit of all living beings (*anām*), not for humans alone (55:10). In fact, the only significant difference between humans and other beings is that humans alone possess consciousness (*taqwa*) and are thus accountable for their actions.

Humans will accordingly be held accountable for any acts of wanton destruction committed against the earth (2:205, 7:85). Wastefulness and overconsumption are also prohibited (7:31), as is hoarding. Water, arguably the most vital natural resource, is to be kept as common property (54:28). Balance (*mīzan*) is to be maintained

in all things, including, presumably, natural systems (13:8, 15:21, 25:2). Failure to do so, consequently, may be argued to be un-Islamic.

In the Hadiths

The Arabs to whom the Qur'an was revealed in the early seventh century CE had a long familiarity with the ecological constraints posed by their native desert environment. Reports about the words and deeds of Muhammad (*hadīths*) indicate that the prophet of Islam possessed both an awareness of these constraints and a sensitivity to the duties of humans toward the rest of creation.

Muhammad received the first of his revelations while meditating in a cave on a mountain outside of Mecca. Thus, as in the case of numerous other seminal religious figures, his insights came within the context of immersion in the natural world. Perhaps the most illuminating of the hadiths in this regard is the one which states, "The earth has been created for me as a mosque [i.e., as a place of worship], and as a means of purification" (*Sahīh Bukhārī*, 1:331). According to another hadith, Muhammad said, "The world is green and beautiful and Allah has appointed you His stewards over it."

A well-known hadith has Muhammad prohibiting his followers from wasting water, even when it is found in abundance and when it is used for a holy purpose such as ritual ablutions (*Musnad ibn Hanbal*, ii, 22). Muhammad also decreed that no more than an ankle depth of water (i.e., sufficient for one season) could be taken for irrigation. Essential resources are to be common, not private property: "Muslims share alike in three things – water, pasture and fire" (*Mishkat al-Masābih*).

Numerous hadiths speak to Muhammad's concern for the interests of nonhuman animals. In regard to the killing of domestic animals for food, he called for swift and conscientious slaughter with a sharp knife (*Sahīh Muslim*, 2/11, "Slaying," 10:739) and not to slaughter an animal within view of its kin. He forbade hunting for sport and frequently reprimanded his followers for abusing or neglecting their

camels and donkeys. He urged his followers to plant trees and cultivate land not only to provide food for humans but for birds and other animals as well (*Sahīh Bukhārī* 3:513). In a hadith which is strikingly similar to a well-known rabbinical saying, Muhammad is reported as saying "When doomsday comes if someone has a palm shoot in his hand he should [still] plant it" (*Sunān al-Baihaqī al-Kubrā*).

In Islamic Law

The legal corpus known as the *sharī'a*, codified by Islamic jurists during the Classical period (eighth to tenth centuries CE), was meant to be all encompassing and thus includes aspects which could be said to deal with environmental protection and management of natural resources. The jurists applied the four principles of Qur'anic injunctions, the example of Muhammad as attested in the hadiths, analogical reasoning, and their own consensus of opinion to the preexisting customary practices of the Arabs and the Persians in particular and to some extent of other Muslim peoples.

The aspect of *sharī'a* law with the most explicit environmental applications may be the institution of the protected zone (*harīm*), which prohibited the development of certain areas, mainly riverbanks, for purposes of protecting watersheds. A related institution is that of the preserve (*hima*), which usually entailed the protection of trees and wildlife. Some traditional *harīms* and *himas* still exist today, notably in Saudi Arabia, but they are much diminished from former times and continue to disappear. The legal texts go into some detail about the distribution of water resources and also devote sections to the "bringing to life" (*ihyā*) of "dead" lands (*mawāt*), including the conditions and rights pertaining to one who engages in such "development."

Islamic law also extends many legal protections to nonhuman animals, including the "right of thirst" (*haqq al-shurb*), which states that they cannot be denied drinking water (Qur'an 91:13). A thirteenth-century work by 'Izz al-din ibn 'Abd al-salam, *Qawā'id al-ahkām fī masālih al-anām*

(*Rules for Judgment in the Cases of Living Beings*), includes what might be called in contemporary terms “an animals’ bill of rights.” Among the provisions are that animals should be properly cared for, not overburdened, kept safe from harm, given clean shelter, and allowed to mate.

Although there is little in the classical legal corpus that could be explicitly categorized as environmental law, there exist within it several basic principles which could, if so interpreted, serve to mitigate some of the main causes of global environmental degradation today. In particular one may cite the principles of minimizing damage, the primacy of collective over individual interests, and the giving of priority to the interests of the poor over those of the rich. While some contemporary Muslims – notably Mawil Izzi Dien and Uthman Llewellyn – have attempted to provide such interpretations, these have not yet found their way into the legal codes of any existing Muslim societies.

In Islamic Philosophy

From around the tenth century CE, Muslim philosophers, familiar with Classical works, appear to have been the ones to coin the Arabic term *tabī‘a* to represent the Latin and Greek equivalents *natura* and *physis*. (The word *tabī‘a* does not appear in the Qur’an.) The derivatives *tab‘* and *mathbū‘* may, on the other hand, have been the source of the Latin pairing *natura naturans* and *natura naturata* (Nasr 1964/1993, p. 9). In Islamic philosophy the distinction between the creator and creation is represented by the terms *haqq* (lit., “divine truth”) and *khalq*. The laws of the universe exist not in and of themselves but rather as expressions of the divine will, understood in Aristotelian terms as the first cause. There are no “secondary” causes; thus, what appear to be the laws of nature are merely the “habits” of created things, which God could alter if he chose. Miracles, accordingly, are seen simply as instances where God chooses to cause things to happen in other than their familiar, habitual manner.

Yet the relationship of the infinite (the creator) to the finite (creation) is neither entirely one of immanence (*tashbīh*) nor one of transcendence (*tanzīh*), since both extremes are incompatible with the ultimate oneness (*tawhīd*) of God. Neither can creation be divine alongside the creator nor can there exist separate realities for each; either case would represent a kind of polytheism (*shirk*) unacceptable in Islam.

The Muslim philosophers largely followed the Greek model of the cosmos, which they understood to be spherical in shape and bounded by the stellar field. The planets, the Sun, and the Moon occupy the middle layers, with the Earth constituting the center. The heavenly world (*al-‘ālam al-ā‘la*), though made up of ether in contrast to the lower world (*al-‘ālam al-asfāl*) which is comprised of the four elements, shares with it the qualities of heat, cold, moistness, and dryness and acts upon it accordingly. The earth’s geography was most often understood in terms of the pre-Islamic Iranian divisions of seven concentric climes (*keshvars*), although the fourfold division of the Greeks and the ninefold version of the Indians were also known.

The Islamic philosophers affirm the position of humans near the top within the hierarchy of created beings, below angels but above other animals, plants, and minerals. Humans are the mediators between the heavenly and earthly realms and a major channel for divine grace. The human body, furthermore, is perceived as a microcosm of the universe, with specific parts of the body being identified with parts of the zodiac and thus subject to their influences.

The so-called Pure Brethren of Basra (*Ikhwān al-Safā*), in their tenth-century treatises collectively known as the *Rasā’il*, write that the study of nature offers proof of God: “Know that the perfect manufacturing of an object indicates the existence of a wise and perfect artisan even when he is veiled and inaccessible to sense perception. He who meditates upon botanical objects will of necessity know that the beings of this reign issue from a perfect artisan” (Nasr 1964/1993). For the Ikhwan, who considered themselves Pythagoreans, numbers were an important means of insight into the ordering of

nature. In one section of their treatise, the Ikhwan present a fictitious court case in which nonhuman animals complain of their treatment by humans. Goodman has drawn attention to the similarity of ecological vision evoked in this tenth-century tract with that of contemporary ecologists (Goodman 1978). The Ikhwan were a marginal group, however, and their views should not be taken to represent the mainstream Islamic thought of their time.

In Sufism

Muslim mystics, known as Sufis, have tended to interpret Qur'anic references to the oneness of God (*tawhīd*) as indicating an underlying unity to all reality. The Andalusian mystic Muḥyi al-din ibn 'Arabi (1165–1240) described creation in terms of “unity of being” (*wahdat al-wujūd*), an idea which won wide popularity among Sufis especially in South Asia where his work remains highly influential. Many mainstream Muslims have found this belief to verge dangerously close to pantheism, however; the seventeenth-century Indian Sufi teacher Shah Waliullah preferred the term “unity of witness” (*wahdat al-shuhūd*) as more clearly maintaining the distinction between creator and creation.

The Sufi notion of the “complete man” (*al-insān al-kāmil*), also elaborated by Ibn 'Arabi, expands the conception of the human being as microcosm of the universe. For Sufis, cultivation of the individual is analogous to cultivation of the cosmos as a whole; thus, one's personal spiritual development can affect the entire world.

To Sufis such as Jalal al-din Rumi (1207–1273), not just animals and plants but the entire universe of creation is alive (Clarke 2003). “Earth and water and fire are His slaves,” he writes in the *Masnavī-yi ma'navī*; “With you and me they are dead, but with God they are alive” (1.838). Nature also speaks, though only the mystics realize this: “The speech of water, the speech of the earth, and the speech of mud are apprehended by the sense of them that have hearts” (1.3279). The conversations of nature are indicative of affective relationships: “You yourself know what

words the sun, in the sign of Aries, speaks to the plants and the date palms/You yourself, too, know what the limpid water is saying to the sweet herbs and the sapling” (6.1068–69). Moreover, the Sufis often employ the symbolism of love (*‘ishq*) to describe the relationship of mutual attraction between the creator and his creation. Yunus Emre, a thirteenth-century Turkish poet, composed the famous line, “We love all creation for the sake of its Creator.”

Many Sufi tales, such as those found in the works of Rumi, Attar, and others, include animal characters, though these are almost always stand-ins for human characteristics associated with particular species. Nonhuman animals are seen as occupying a level below humans, and the “animal soul” of the philosophers is equated by the Sufis with the “lower self” (*nafs*), or one's own baser instincts which along the path of spiritual development one strives to overcome.

Contemporary Islamic Environmental Ethics

While it is important not to romanticize the past – Muslims, like people of all cultures, have not always followed the spirit or the letter of their sacred laws – it would appear from the above that premodern Islamic societies possessed something that might be considered in contemporary terms as having constituted an environmental ethic. And while one may likewise remain skeptical of arguments that Western imperialism alone is to blame for the erosion of traditional norms throughout the Muslim world, it does seem to be the case that traditional Islamic directives enjoining care and restraint in regard to the use of resources have become less apparent in the modern period.

In short, not only are Muslim societies today *not* models of environmental consciousness, in many cases they provide examples of the worst sorts of environmentally destructive lifestyles and development policies. Many of the most severely degraded environments in the world today are those in which Muslims constitute

a majority of the population. While overall per capita consumption and pollution rates are generally less than in Western industrial societies, Muslim countries mostly suffer from acute environmental problems connected with poverty, overpopulation, and outmoded technologies.

Unfortunately, it is also true that Muslim societies today are faced with so many severe problems of all kinds – political, social, and economic – that environmental protection often seems at best a secondary concern. Few Muslims have yet come around to the way of thinking expressed by Stanford biologist Paul Ehrlich, when he stated that “the environmental crisis is the playing field on which all other problems are played out,” or the popular environmentalist image in which the various human struggles going on in the world today are like “fighting over deck chairs on the Titanic.” We are so preoccupied with dealing with the threats approaching us head on that we fail to notice what is happening under our feet.

To be fair, Westerners too have been extremely slow to recognize the severity of the threat posed by global environmental degradation. This is more true than ever today, as the government of the United States of America, the world’s number one polluter, holds ever more firmly to a Pollyanna-esque notion that environmental concerns are overstated and trumped by the unrivaled importance of permanent economic growth. It seems significant that in March 2005, the publication of the so-called Millennium Ecosystem Assessment, in which a 5-year study by 1,360 scientists from 95 countries concluded that human activities have severely compromised two-thirds of the earth’s ecosystems in only the past 50 years, made front-page headlines in Europe and elsewhere in the world but was almost completely ignored by the mainstream media in the USA.

The USA is the world’s richest country, and environmental degradation is typically less worrisome to the rich who can mostly shield themselves from its effects than it is to the poor who suffer from environmental problems most immediately and most severely. In the developing world, the environmental crisis is

often experienced most profoundly by rural women, who are the primary users of natural resources (and whose husbands may be quite disconnected by comparison, away working in urban factories). At the same time, rural women tend to be the most disempowered members of traditional societies, thus the least able to react to the crisis.

Ironically the United States, while remaining the world’s major agent of environmental destruction as well as the leading proponent of unsustainable economic policies and practices, is also the original home of environmentalism in its modern sense. Environmental consciousness, in its contemporary form, emerged in the late nineteenth century among Americans such as Henry David Thoreau, John Muir, and Theodore Roosevelt. Revisionist philosophies which placed humans within and not above natural systems were articulated by Americans such as Aldo Leopold in the 1940s and Edward Abbey in the 1970s. Contemporary environmentalism, as exported to the rest of the world, is thus largely an American product.

This point has not gone unnoticed by environmentalists elsewhere. In a 1989 article in the US-based journal *Environmental Ethics*, Indian sociologist Ramachandra Guha argued that whatever its inherent merits, an environmentalism derived within the particular history and culture of North America cannot simply be applied as a one-size-fits-all model to the rest of the world. The attempt to do so – seen in such examples as the creation of national parks from which human inhabitants are forcibly expelled – too often constitutes a “direct transfer of resources from the poor to the rich” (Guha 1989, p. 75).

It hardly comes as a surprise, then, that environmentalist policies and initiatives in the Muslim world are often seen as merely another example of Western imperialism, an attempt by foreigners, foreign interests, or foreign puppets to meddle in the affairs of Muslim communities for purposes of exploitation and control. It would seem that under such circumstances, environmentalism in Muslim societies would have to develop in an indigenously derived form

seen as locally relevant, if it hopes to take root and flourish. Unfortunately examples of home-grown environmentalism are not yet easy to find in the Muslim world, though they are not nonexistent.

Probably the credit for first beginning to think about the environmental crisis in Islamic terms should go to Seyyed Hossein Nasr, an Iranian-American academic who has been preoccupied with the effects of human activities on natural systems since before Rachel Carson, during his student days in Massachusetts during the 1950s when he would trace Thoreau's footsteps around Walden Pond (Nasr 2003, p. 85). A historian of philosophy and science, Nasr, was struck by how much had changed since Thoreau's time and began to feel that there was a marked difference between Islamic science, in which the pursuit of understanding nature was seen as a sacred undertaking, a way of better knowing the mind of God, and the desacralized scientific approach of the post-Enlightenment West in which nature was seen as mechanical, devoid of life or inherent meaning, and existing only to serve human ends.

Nasr spelled out this distinction in his book *Science and Civilization in Islam* and other works, even preceding by several months Lynn White Jr.'s famous critique of human exceptionalism in Western religions, a 1967 paper titled "The Historical Roots of Our Ecologic Crisis" (White 1967), with a similar argument in a lecture series Nasr gave at the University of Chicago in the summer of 1966 (Nasr 1967). Over the past four decades, Nasr has continued to describe the environmental crisis as one that originates as a crisis of values; his works are cited widely by Muslim environmentalists and as a representative authority by Westerners seeking to include "the Islamic perspective" in discussions on the environment.

The main shortcoming of Nasr's contribution has been that he has always written predominantly for a Western audience of non-Muslims, serving first and foremost as an apologist for Islam. Those Muslims who have read him have almost always read him in English, as his works have been little translated into Arabic or even his own native Persian. His case exemplifies the

paradox that, even among Muslims seeking to derive an environmentalism from within their own tradition, the initial impetus and context is often the West.

The first specifically Islamic treatise on environmental protection, composed by a team of Islamic scholars in Jeddah, Saudi Arabia, in 1983, was commissioned by a Swiss-based environmental organization, the International Union for the Conservation of Nature and Natural Resources (IUCN) (Kader et al. 1983). The resulting tract, which consisted of only 30 pages of text, was very poorly distributed, and its authors have since acknowledged that their efforts to have its findings adopted by policy-makers in Muslim countries have largely failed.

A second effort to articulate Islam-based environmental values came at the instigation of another Western organization, the Worldwide Fund for Nature (WWF). The WWF organized a symposium in Assisi, Italy, in 1986 on environmental values in world religions, to which a Muslim representative was invited and who composed a one-page statement on Islam and the environment (Nasir 1987, p. 47). Later, the WWF expanded their project to commission short edited books of articles on religion and the environment, one book for each major religion. To edit the Islam volume, they approached Fazlun Khalid, a British Muslim of Ceylonese origin who had developed a strong interest in environmental issues through reading the works of Nasr and a number of Western environmentalists.

The WWF volume edited by Khalid and published in 1992 under the title *Islam and Ecology* contained a half dozen brief essays by practicing Muslims which took note of Islamic teachings on the environment and offered explanations for the environmental crisis based on such things as Islamic critiques of the global economy (which, being based on the taking of interest and the unlimited creation of credit, they claimed as fundamentally un-Islamic) (Khalid and O'Brien 1992). Again, this little book was poorly circulated – though it has since been issued in Turkish and Indonesian translations – and was known and used mainly by

Western environmentalists as a statement of “the Islamic position” on environmental protection.

The most sophisticated attempt yet to discuss environmental values through the lens of the world’s religious systems was undertaken in the late 1990s by two professors at Bucknell University, Mary Evelyn Tucker (a specialist in Confucianism) and her husband John Grim (an expert on Native Americans). Tucker and Grim obtained funding from a variety of sources which enabled them to organize a series of ten international conferences on religion and ecology, which were held at Harvard University Divinity School from 1996 to 1998. For the Islam conference, which occurred in May 1998, Grim sought out the organizational assistance of Fazlun Khalid, who drew on his growing international network of Muslims concerned with the environment to come up with a list of participants.

The Harvard conferences, perhaps to be expected of an initial foray into a new field, provided mixed results. At the Islam conference, it was hard not to feel that many of the participants were less interested in saving the environment than they were in taking advantage of an all-expense-paid trip to Harvard. In their presentations many referred to the environment only passingly, some not at all. Though other axes were ground, no hard questions were asked about the treatment of the environment in contemporary Muslim societies, and all problems were blamed on Western interference, Western values, and the erosion of traditional Islamic norms. The dominant theme of the conference was that Islam provides everything necessary for the appropriate management of natural resources and that if Islam were widely and properly practiced, then there would be no environmental crisis to talk about. Issues such as human population control, lifestyles of overconsumption, and animal rights, when briefly raised, were loudly dismissed out of hand by certain vocal participants and not revisited.

Nevertheless, a number of genuinely committed Muslim environmentalists did attend the conference, even if their voices were not prominently heard there. The event at least resulted in both the publication of an edited book, like its predecessor titled *Islam and Ecology* but at 584

pages much more extensive (Foltz et al. 2003), and in the strengthening of a global network of Muslim environmentalists which continues to expand today. Among them can be counted, in addition to Fazlun Khalid, Uthman Abd al-Rahman Llewellyn, an American convert who has spent many years working as an environmental consultant for the government of Saudi Arabia; Turkish theology professor İbrahim Özdemir, author of several books on environmental ethics and now Undersecretary of Education for the Turkish government; Safei El-Din Hamed, professor of landscape architecture at Texas Tech and former consultant to the Egyptian government and the World Bank; and Mohammad Aslam Parvaiz, founder-director of the Islamic Foundation for Science and Environment in Delhi. Özdemir has since arranged for a Turkish translation of the Harvard *Islam and Ecology* volume, while Parvaiz has commissioned an Urdu version for use in the Islamic seminaries of India. Another longtime Islamic environmentalist, Iraqi-born law professor Mawil Izzi Dien, who did not attend the conference but who submitted a paper for the published proceedings, has been attempting to establish a Centre for Islam and Ecology at the University of Wales. Izzi Dien contributed to the 1983 Jeddah tract and is the author of the first book-length treatment of Islam and the environment, titled *The Environmental Dimensions of Islam*, which was published in 2000 (Izzi Dien 2000).

By far the most significant efforts in disseminating an Islamic ethic of the environment on a global scale have been by Fazlun Khalid. Beginning with the establishment of the organization he founded in the early 1990s, the Islamic Foundation for Ecology and Environmental Sciences (IFEES), based in Birmingham, England, this former British civil servant has spent the last decade of his retirement endlessly traveling around the world conducting environmental education seminars in Muslim communities from Saudi Arabia to Indonesia. A project conducted by Khalid among the Muslim fishermen on the East African island of Zanzibar was described by BBC News in early 2005 as a remarkable success.

Such efforts by practicing Muslims, who happen to be environmentalists and therefore seek to

articulate their environmentalism in Islamic terms, may be weighed against initiatives in countries where the environmentalists concerned just happen to be Muslims (Foltz 2005). The international environmental organizations WWF and IUCN, for example, both have offices in a number of Muslim countries. (The IUCN Karachi office is the largest in the developing world.)

As might be expected, organizations that are Western in their origins, outlook, and approach are likely to attempt projects which reflect their Western orientation. Equally predictably, their successes have been mixed, when they have not – as in IUCN Pakistan's attempt to enlist Pathan religious scholars in teaching environmental ethics in religious schools – been acknowledged failures. One significant aspect of the constraints faced by international environmental organizations operating in Muslim countries is that they tend necessarily to be grant driven. That is to say, because they rely heavily on grants to carry out their works, they must devise projects which may reflect more the interests of granting agencies than they do the actual needs of the societies in question.

An exception to this phenomenon can be found in Iran, where NGOs are severely restricted in their ability to solicit or obtain external funding because of a long-standing US-led economic embargo. As a result, environmental organizations in Iran have emerged in a context of independence and localism. Indeed, Iran would seem to offer the most successful example in the world today of a truly home-grown environmentalism (Foltz 2005).

Civil society in Iran benefited greatly from the election of reformist president Mohammad Khatami in 1997. Since then, over 200 new environmental organizations have been officially recognized by the Iranian government. The government of the Islamic Republic itself has promoted an environmentalist rhetoric which is among the most sophisticated and progressive in the world, even explicitly calling for an Islamic approach to environmental ethics, although its rhetoric has not been backed up by action in many cases.

Environmentalism in Iran is seen most tangibly in the proliferation of environmental NGOs, many of which, such as the Green Front of Iran (GFI), have been remarkably effective in raising public awareness and carrying out environmental protection campaigns. And while the government continues to be seen by most Iranians as all talk and no action, Iranian environmentalists at least enjoy the theoretical support of the Islamic state.

While Iran's home-grown environmentalism seems to hold unique promise in the Muslim world today as proof that indigenous, non-Western models can indeed succeed, paradoxically the conditions of enforced independence which gave rise to Iran's unique environmental movement are little appreciated by most Iranians, who are eager to overcome their 25 years of forced isolation and climb aboard the juggernaut of economic globalization. With Iran's entry into the WTO newly on the table for discussion and a president for whom environmentalism seems a lesser priority than challenging the West, the future of Iranian environmentalism may be in question.

In conclusion, a plurality of models currently exists for environmentalism across the Muslim world. Unfortunately, none yet appears up to the task of reducing the momentum of ecologically devastating modernity, which continues its head-long plunge toward global catastrophe. But if there is any hope at all for the world's environmental movements to play a role in slowing the present destructive trends and steering human society toward more just and sustainable alternatives, the planet's 1.2 billion Muslims demonstrably have cultural resources to draw upon which are both compatible with their traditions and hold promise for meeting emerging needs.

Description

Broadly speaking, the term “ecology” connotes a worldview that emphasizes interaction and connectedness: all living and nonliving things are integral parts of the biospherical web; their essence or identity is an expression of connection and context, so that to understand their makeup, it is necessary to consider relations between parts and not just the parts themselves. All life-forms – including *Homo sapiens* – result from the same processes, and given the affinities between humans and nonhumans, the value of nonhumans is not merely instrumental as a resource utility for human beings. It is precisely this misguided instrumental attitude toward the natural world that has led humans to cause serious damage for the earth, a situation which calls for environmental ethics. In a narrower sense, the term “ecology” refers to the science of ecology which has a specific history consisting of individual scientists practicing ecology within definite social and institutional milieus. In popular parlance, “ecology” has become vaguely synonymous with “environmentalism” and denotes an awareness of the current ecological damage to the earth and its inhabitants and the actions necessary to remediate the damage.

Jewish Environmentalism

A Jewish environmental movement emerged in the early 1970s as an apologetic defense against the charge of Lynn White Jr. that the Judeo-Christian tradition, rooted in the Bible, was responsible for the current ecological crisis. In defense of Judaism, Jewish theologians have argued that White and other environmentalists either misread the Hebrew biblical text or lack any knowledge of postbiblical Judaism. An accurate and informed reading of Jewish sources shows that the Jewish religious tradition, and especially the Bible, is replete with ecological wisdom and that its environmental ethics can be used as a basis for sound ecological policies.

While Judaism views the human as the zenith of creation, the Jewish faith does not give license to exploit the earth's resources. Rather, Judaism articulates an ethic of responsibility that enjoins humanity to take care of the world God has created. The biblical narrative of the Garden of Eden, in which the first created earthling was placed "to till and protect it" (Gen. 2:15), serves as a paradigm for the desired relationship between humanity and the natural world: humans must tend to and care for the natural world of which they are part.

Since the 1970s, Jewish environmentalists have mined the Jewish literary tradition for its ecological wisdom, reinterpreting the Jewish heritage in light of environmental concerns and values. In particular, the prophetic commitment to social justice and care for the poor inspired leftist political thinkers, chief among them Arthur Waskow, to preach a Jewish-, religious-, and leftist-oriented environmentalism. Under the broad concept of "eco-kosher," Waskow has integrated a wide-ranging critique of unjust social practices with deep concern for the Earth and its natural resources and compassion for the socially marginal. In 1993, several Jewish environmental organizations coalesced into the Coalition on the Environment and Jewish Life (COEJL). With a membership of about 10,000, this umbrella organization has attempted to educate Jews about environmental matters, inspiring Jews to lead environmentally sound lives, beginning with the greening of synagogues and calling Jews to lend their support to various legislative organizations and to enter into interfaith dialogue on environmental matters. In the past two decades, several Jewish organizations and educational initiatives in North America (e.g., ALEPH, Alliance of Jewish Renewal, Isabella Freedman Center, Hazon, Kanfey Nesharim, Shalom Nature Center, Tel Shemesh, and others) have attempted to cultivate a Jewish ecological outlook and a program for Jewishly environmental activism rooted in Jewish values.

However, the message that Judaism can be part of the solution to the environmental crisis

and that Judaism approaches the environmental crisis in its own distinctive manner has been slow to spread. Jews either assume that Judaism has little to say about environmental matters or presuppose that Judaism and environmentalism are inherently incompatible. The inherent tensions of Jewish ecological discourse are most evident in the State of Israel. A strong theme within early Zionism conceived the return to the Land of Israel as the return of the Jews to nature, but the complex situation in the modern State of Israel illustrates the paradoxes of Zionism. On the one hand, intimate familiarity with the landscape of the land, its flora and fauna, and the concern for the preservation of the physical environment are popular among secular Israelis, but they are not legitimized by appeal to the religious sources of Judaism. For secular Israelis, attention to environmental issues has more to do with western orientation and links to the environmental movements in Europe and North America than with Judaism. On the other hand, Jews who are anchored in the Jewish tradition tend to link their love of the Land of Israel to the creation of a religious-nationalist vision, which has little to do with environmental values and sensibilities. In fact, these religious-nationalist groups have no qualms committing various environmental sins (e.g., uprooting ancient olive groves) in order to advance their nationalist agenda (i.e., the settlement of Greater Israel) at the expense of the nationalist agenda of the Palestinians. The ongoing Israeli-Arab conflict and especially the Israeli-Palestinian conflict have exacerbated the environmental challenges in the Land of Israel, but, conversely, acute environmental problems such as water shortage that affects Arabs, Israelis and Palestinians have actually inspired some promising Israeli-Arab-Palestinian collaboration. In the past decade, Jewish religious environmentalists have established various educational efforts (e.g., Heschel Center for Education and Environmental Leadership and *Teva Ivry* [Hebraic Nature]) to ground environmental activism in the religious sources of Judaism.

Today, a small but growing body of environmental Jewish discourse articulates a distinctive Jewish presence in the environmental conversation about religion and ecology worldwide. In the State of Israel, a robust environmental movement is involved not only in environmental education and advocacy but also in legislation and political action. Yet in both the State of Israel and the Diaspora, the Jewish environmental movement takes the environmental crisis as a fact to which humans must respond; the movement does not engage the ecological crisis as a scientific question. Scientific findings about particular environmental problems such as soil corrosion, extinction of species, loss of biodiversity, deforestation, or pollution of air, water, and soil are used as evidence to chart the appropriate courses of action. The scientific data about the physical environment are coached neither as “old ecology” (i.e., the view that nature exhibits inherent harmony, order, and beauty) nor as “new ecology” (i.e., a view that highlights the “dark side of nature” due to predation, competition, struggle, conflict, and strife). The call for preservation and protection of natural resources or to find political solutions to growing environmental problems is rooted not in the science of ecology but in the Jewish commitment to justice and the Jewish ethics of responsibility, whether these are anchored in the Jewish religious tradition or given a secular interpretation. Ethics takes precedence in Jewish environmentalism today.

Torah Versus Nature in Premodern Judaism

The complexity of Jewish attitudes toward the natural world could be traced to two foundational beliefs of Judaism: first, that God created the world and continues to manage it and care for it, and second, that God revealed His will to Israel, the chosen people, in the form of Torah. The dominant doctrine of creation insists that God is *not* part of nature and that nature is *not* intrinsically holy. Nature only points beyond itself to the Creator God who has entered a special relationship with one species – the human species – and with one

group of humans, Israel, namely, the covenant. As part of His covenant with Israel, God revealed the law that specifies how Israel is to treat the natural world. These commands constitute the Jewish religious environmental ethics that includes the following principles: First, the world belongs to God, its Creator, and humans are but temporary tenants who should treat God’s world with care. Second, humans, who are created in the image of God, must follow divine commands and protect God’s creation from wanton destruction (*Bal Tashchit*). Third, humans should imitate God who rested at the end of the act of creation; humans and their domestic animals must rest on the Sabbath and extend rest to the Earth in the sabbatical year. Fourth, humans must prevent needless suffering of animals (*tza’ar ba’aley hayim*), even though humans are allowed to eat certain animals which should be killed and prepared in a certain way. Finally, how humans care for the weak and vulnerable of their society determines the well-being and fertility of the earth. These principles are applied first and foremost to the Land of Israel, the collateral of God’s covenant with the chosen people; when cruelty and greed exceed what the land can bear, God exiles the people of Israel from the Land of Israel.

Although the ecological wisdom of the Bible could inspire sound environmental policies, the belief that God revealed His will to Israel in sacred texts also set Judaism as a religion of a Book in which nature was understood, experienced, and interpreted through the prism of Scripture. From the priestly reforms that produced the Book of Deuteronomy, through the Pharisaic interpretation of Judaism during the Second Temple, and into the rabbinic Judaism of the Talmudic period, Judaism emerged as a scholastic culture that over time brought about the increased alienation of Jews from the natural world. In rabbinic Judaism, the Torah was regarded as the sacred medium for communication between God and Israel and the exclusive object of love, devotion, and veneration. To worship God, Israel should study the Torah and behave according to its commandments as expounded in the authoritative interpreters of the Torah, the rabbinic sages, and their heirs through the generations.

The exclusive study of the Torah and the acts that follow from it stand in some tension with the worship of nature (Mishnah Avot 3:7).

The rabbinic movement created a comprehensive lifestyle that was text-centered, a life of prescribed commandments of Torah study. For observant Jews in the premodern world, nature was good but not holy; it could be made holy, or sanctified, through the observance of divine commands that pointed to the divine Creator as the source of meaning and value rather than to nature. Nature (or what “is”) does not dictate what ought to be; only divine revelation articulates the moral norm (what “ought” to be). Historical circumstances further contributed to the disconnect between Jewish communal life and the physical environment: the exile of the Jews from the Land of Israel, urbanization of the Hellenistic world during which rabbinic Judaism came into existence, the occupational shift from agriculture to commerce in the Islamic world, and the restriction on Jewish ownership of land in the Christian world. All of these factors brought about growing alienation from and indifference to the immediate natural environment in which Jews lived. While caring little for the environment where they actually lived, Jews continued to yearn to return to the Land of Israel in the messianic age.

In the middle ages, Jewish philosophers theorized about nature. Especially in Muslim lands, rationalist philosophers were very interested in the natural world as an object of study since in the regularity and orderliness of nature one could discover how God manages the world and come closer to the knowledge of God. Jewish rationalist philosophers were not only interested in the laws of nature as explained by the physics of Aristotle, but they also held that the hidden meaning of the Torah means what natural philosophy, that is, Aristotelian science, teaches. In the middle ages, the study of the laws of nature was seen as a religious obligation.

The medieval worldview and its culture ended for Jews only in the eighteenth century with the emergence of the modern nation-state that could not tolerate the semiautonomous communal life of Jews. From the end of the eighteenth century

and throughout the nineteenth century, European Jews began to demand an end to centuries of discrimination, exclusion, and marginalization and demanded civil rights and social inclusion. By the 1870s, Jews in Western and Central Europe indeed received civil rights, but granting civil rights to Jews did not entail social acceptance; the emancipation gave rise to ongoing internal debate about the meaning of Jewish identity, and the emancipation unleashed a backlash in the form of racial anti-Semitism. All these factors played a role in how “nature” was construed in Jewish discourse during the nineteenth century.

“Religion” and “Science” in Modern Judaism: The Debate about Evolution

As Europe made it possible for Jews to integrate into majority society and culture, Jews flocked to the universities, whose doors had previously been closed to them. Many Jews were attracted to the natural sciences, especially the new disciplines of chemistry, microbiology, and medical biology. In some scientific fields, Jews were disproportionately represented and reached outstanding achievements; other fields were shaped entirely or mainly by Jewish scientists. For Jews who wished to become part of European culture, modern science became a substitute for religion, although, ironically enough, it was the lifestyle of traditional Judaism with its insistence on study, meticulous observance of laws and commitment to the pursuit of truth that generated the personality type suitable for the rigors of scientific inquiry. Since academic excellence did not guarantee academic appointments or social acceptance, conversion to Christianity was rather common, being seen as a path toward full integration that many Jews coveted. For those who remained loyal to the ancestral tradition, the meaning of Jewish identity became hotly contested, resulting in diverse ways of being Jewish. Some insisted on the modernization of Judaism from within (Reform); others insisted on the timelessness of Judaism, although they accepted the validity of modern culture and

consented to superficial changes in Jewish practices (positive-historical school and neoorthodoxy), and still others rejected the winds of change and erected an ever higher fence around the Torah to defend Judaism from modernity and modernization (ultra-Orthodoxy).

These developments brought a cleavage between the natural sciences and religion in Judaism, which was simply unknown in the premodern world. Unlike Maimonides and the late medieval Aristotelian Jewish philosophers, nineteenth-century Jewish theologians, especially if they were associated with the movement for religious reform, did not consider the study of nature a religious obligation. As “science” and “religion” grew apart from each other, theologians held that scientific knowledge about nature was to be found in the laboratories of the modern university rather than the sacred texts of the Jewish tradition. The role of the theologian was not to speculate about the natural world, but to defend the rationality of the scriptural tradition which had come under the scrutiny of yet another modern science: the science of history. Historicism in the nineteenth century invalidated many religious claims by questioning the divine origin of scriptural texts, showing them to be but human-produced documents.

In contrast to their Protestant counterparts, Jewish theologians who agitated for Reform Judaism did not turn to the Book of Nature to justify their claims but rather focused on the rationality of the doctrine of revelation. They continued to see the Bible as a revealed text, although they challenged the authority of its rabbinic interpretation. Without loyalty to revealed Scripture, they believed, Jewish religious identity could not be maintained. Thus, Ludwig Steinheim (d. 1866), Solomon Formstecher (d.1889), and Samuel Hirsch (d. 1889) all attempted to prove that revelation is logically plausible and that Judaism is the highest expression of universal, rational, and moral religion. They focused on the meaning of revelation and employed the philosophy of Kant, Hegel, and Schelling to articulate the intellectual content of the Jewish religion. The doctrine of creation, which was the primary context for the Jewish reflection on nature among medieval and early

modern thinkers, became less important to these theologians because they presented Judaism as a spiritual religion that transcends nature. Presumably, only pagan religions identify God with nature, while rational, ethical Judaism based on the teachings of the prophets is the ultimate rejection of paganism including its Christian manifestations.

The core theory of the science of ecology – the theory of evolution – generated diverse Jewish responses. In Europe, especially in Germany, nineteenth-century theologians of the Reform Movement, who endorsed modernization and acculturation, defended Judaism as a rational religion and insisted that in principle, Judaism has nothing to fear from modern science. Although a radical and rationalist form of Reform Judaism had developed in Germany, viewing Judaism as faith in ethical monotheism, it did not necessarily entail openness toward Darwin’s theory of evolution. Abraham Geiger, for example, the leading Reform theologian, rejected outright the transmutation of species, using standard arguments from the 1860s: the moral and rational gap between humans and animals, the harmony evident in organic nature, and the apparent incapacity of natural forces to produce new species. However, the historical gist of the theory of evolution was adopted by several Jews (e.g., Zecharias Frankel), who sought modernization of Judaism and who argued that the Jewish religion developed over time.

In Victorian England, the coherence of Judaism and science (including the theory of evolution) was the standard view of Anglo-Jewry. The presumed alliance between Judaism and science was expressed in the pages of the *Jewish Chronicle* and fits well with the assimilationist tendency of the rising middle-class English Jewry. In contrast, the less assimilated and generally poorer members of the community, who tended to read the *Jewish Record*, were more aware of the challenge that the science of evolution posed to Judaism. The communal leaders insisted on harmony between Judaism and science, as a survival strategy against anti-Semitism, on the one hand, and assimilation, on the other hand, but a radical, rationalist Reform Judaism did not take root in

England. There was only one rigorous scientific defense of the theory of evolution by the eminent Jewish naturalist, Raphael Meldola, who considered the theory of evolution to be in full accord with the highest standard of scientific method and who saw no incompatibility between being an evolutionist and a materialist and being a Jew, albeit an assimilated one. He was the exception rather than the rule.

In America, the debate about Darwin's theory of evolution was much more rigorous, but it emerged only after the publication of the *Descent of Man* in 1871. Rabbi Kaufmann Kohler (d. 1926) endorsed the theory of evolution which he viewed as a scientific proof for the Reform understanding of Judaism, that is, as a progressive religion that evolved in morality and conceptions of God from biblical times to the present. Kohler ignored the theory of natural selection and defined Darwinism as "the natural law of progressive development of life under favorable conditions." The major critic of evolution among Reform Judaism, Rabbi Isaac Mayer Wise (d. 1900), understood natural selection to be a natural law in which survival of the strongest prevails. For him, nature was indeed a "battle ground" which robbed the moral law as taught by Judaism of its legitimacy. Wise developed his own theory about the history of life which acknowledged that the Jewish religion like nature is bound by a law of evolution, meaning that it progresses from lower to higher forms. However, he did not adopt the theory of progressive revelation and opposed the notion of gradual continuous transmutation of species.

At stake in the debates about evolution were not the varying theories of evolution, but the implications of the concept of progress for the Jewish religion. A few Reform rabbis followed Wise in rejecting evolution on the ground that it is improbable, but several traditionalist Jews began to consider arguments against evolution on the basis of specific references in Genesis. The traditionalists understood that the evolutionary theory denied the belief that God created the world according to his free will and insisted that the materialism and atheism associated with evolution also undermine human accountability before

God which results in nihilistic and immoral behaviors. The traditionalists gave rise to Conservative Judaism which offered a way for numerous Jewish migrants from Eastern Europe to Americanize while remaining loyal to their traditional Jewish lifestyle.

In the twentieth century, the theory of evolution has generated much less debate among Jews than among Christians. Leading evolutionary biologists and ecologists – Stephen Gould (d. 2002), Richard Lewontin (b. 1929), Lynn Margulis (b. 1938), and Lawrence Slobodkin (d. 2009) – are born Jews, but their scientific research is not informed by the sources of the Jewish tradition, since they tend to see science and religion as two "nonoverlapping magisteria." Conversely, there are Jewish scientists (especially physicists) who are religiously committed and scientifically educated – Nathan Aviezer, Gerald Schroeder, and Judah Landa – who have attempted to show that the doctrine of evolution does not violate the literal meaning of the biblical creation narrative. For them, there is no conflict between the Torah and science, only between rabbinic interpretation of Torah and science. When the Bible is properly interpreted, these seeming problems "dissolve into nothingness." Today, the ultra-Orthodox world has become less and less interested in contemporary science and more willing to interpret the biblical text literally. Thus, in 2004, the works of the Orthodox rabbi Nossin Slifkin, who attempted to integrate the belief that the earth is millions of years old with Jewish traditional sources, generated a heated controversy and were banned by some authorities. As a result, the teaching of evolution in Orthodox and ultra-Orthodox schools has clearly stalled, and these communities show relatively little interest in ecological or environmental matters. The situation is somewhat better in Israel, where rulings by Ultra-Orthodox authorities at times impinge on environmental issues.

Ecological Strands in Modern Judaism

Ecological thinking is rather marginal in modern Jewish thought, but several modern Jewish

thinkers could be labeled “ecological” because they highlight interaction and connectedness between all living and nonliving things, they reject the notion that nature has only instrumental value as a resource utility for human beings, and they promote a view of nature as a source of moral obligation and/or spiritual vitality. A few examples will illustrate ecological tendencies in Modern Orthodoxy, Zionism, and the Jewish Renewal Movement. The impetus for these ecological reflections does not come from the science of ecology, but it is possible to find within modern Jewish theology a few ecological voices. Some of them view nature as holistic, stable, and balanced, while others recognize that nature as a dynamic, perpetual flux.

Modern Orthodoxy

Modern Orthodoxy was founded in Germany by Samson Raphael Hirsch (d. 1888), as a response to the movement for religious reform. While Hirsch endorsed the Jewish struggle for emancipation and advocated openness toward European secular culture, he defended the traditional doctrine of “Torah from Heaven” and rejected the reformers’ critique of rabbinic Judaism or their tendency to discard traditional practices and introduce new rituals. In accord with rabbinic Judaism, Hirsch argued that God, the Creator of the world, gave humans the *right* to rule nature, but that this right came with the *duty* to treat God’s created order in accordance with divine will. According to Hirsch, the human is part of nature, indeed a “brother to all creatures,” but like the first born in a Jewish family, the human also has special privileges and obligations. Hirsch held that human mastery over nature is about the fulfillment of the human rational, God-given, free will, but the human right of mastery over nature depends on the extent to which the human will corresponds to God’s will. The Torah itself thus discloses how nature is to be treated with justice and respect.

In his classification of Jewish laws, Hirsch placed the commandment “Do Not Destroy” (*bal tashchit*) at the head of the section on the *Hukkim* (decrees), which were legislated by God primarily for the protection of nature from human

avarice and exploitation. Heedless destruction of nature reflects human arrogance and rebellion against God, but the laws of the Torah assure that humans behave wisely and judiciously to protect the integrity of the natural world and its perpetuation. For Hirsch, the created world exhibits not only inherent purpose but also orderliness, intelligence, and interdependence. Given the remarkably wise design of the universe, humans have an obligation to protect the natural world. Indeed, Scripture prohibits copulation of diverse animals, grafting of diverse trees, yoking together of diverse animals, wearing of wool and flax, and mixing of milk and meat. These laws are rooted in the act of creation when God separated His creatures “each according to its kind.” Through the Torah, the Creator of the world functions as the “regulator of the world”; the human who was appointed as the “administrator” of God’s estate executes the rules that ensure protection of nature. In Hirsch’s analysis of the *Hukkim*, nature serves as a model for observance of divine commands and places its own demands or commandments on humans. Hirsch’s approach thus exemplifies how Modern Orthodoxy can support Jewish religious environmentalism.

Zionism

Jewish religious environmentalism accords a place of honor to the Land of Israel, the Holy Land, which serves as collateral in the covenant between God and the people of Israel. The Bible, however, makes clear that the Land of Israel was given to Israel conditionally: so long as Israel observes God’s will and follows His commandments, including the commandments for the treatment of nature, and the land remains fertile and provides the people of Israel with abundance. But when Israel rebels against God and sins against God, the Land becomes infertile and desolate; when sinfulness abounds, God exiles Israel from the Land of Israel. Throughout their long exilic existence, Jews have yearned to return to the Land of Israel, but they postponed the fulfillment of this dream to the Messianic Age of the remote future. At the end of the nineteenth century, however, Zionism rebelled against the passivity of traditional Jewish messianism by insisting that Jews take the

initiative to leave their countries of residence and settle in their ancestral home. Only in the Land of Israel could the Jews become a normal nation with its own political sovereignty, spoken language, and unique culture. For Zionist ideologues, the return of the Jews to the Land of Israel was not only a secularization of the messianic dream, it was also a call for the return of the Jews to nature in order to create a new “muscular Jew,” a physically strong, fearless Jew who celebrates the rhythms of nature and derives vitality from nature.

The return of nature played a central role in the original and highly creative thought of Aharon David Gordon (d. 1922), the spiritual leader of Labor Zionism. Although he grew up in an Orthodox home in Russia, Gordon studied European philosophy and literature and was particularly influenced by Friedrich Nietzsche, Henri Bergson, and Leo Tolstoy. Settling in Palestine in 1904, Gordon joined the agricultural settlements and experienced the hardship of pioneers’ life in order to exemplify his call not just for the Jews but for all of humanity. For Gordon, the Jews’ return to their land symbolized humanity’s return to nature and the renewal of the relationship (indeed the covenant) between humanity and nature which was destroyed by culture, especially modern, urban, and industrialized culture. Gordon contended that human beings should strive “to live with and in nature,” because the universe is an organic totality enlivened by divine energy that pulsates through all levels of reality. Emerging out of the organic totality, humans have reached the most developed state of being: culture and self-consciousness. Yet these are also the causes for human alienation from nature. The human tragedy is especially severe in the case of Jews because they seek to assimilate into western Christian culture, denying their roots in the Land of Israel, the Jewish nation, and in the Hebrew language. Only agriculture and farming could reconnect modern, alienated Jews to the sources of cosmic creativity, enabling them to live most authentically as Jews as well as human beings, an ideal he exemplified in his own life.

Gordon’s thought has a strongly pantheistic character, which could be traced to various intellectual sources, both Jewish (i.e., kabbalah and

Hasidism) and non-Jewish (i.e., Bergson and Tolstoy). He viewed nature as an organic totality out of which emerges human consciousness, and he called the totality of nature *havaya*. Literally, this means “being” but is in fact the four letters of the Tetragrammaton arranged in a different order. Secularizing the notion of divine immanence, Gordon understood “being” as a dynamic, ever-changing living force in constant flux that pulsates throughout all levels of reality. Humans can experience the hidden aspect of nature only through direct intuition arising through manual labor which overcomes the alienation of mankind from nature. For Gordon, the regeneration of humanity and the regeneration of the Jewish people could come only through the development of a new understanding of labor as the source of genuine joy and creativity.

Jewish Renewal Movement

The Zionist call for the return of the Jews to nature illustrates the traditional Jewish idea of *teshuvah*. The term is usually translated as “repentance,” but its Hebrew stem connotes both “to return” and “to reply,” so that *teshuvah* means both a movement of return to one’s source, to the original paradigm, and simultaneously a response to a divine call. *Teshuvah* thus involves a spiritual reorientation or a transformation of the self away from an inauthentic way of life lacking creative force and toward the authenticity that is characterized by continual creativity and renewal. In America, during the second half of the twentieth century, this concept gave rise to the Jewish Renewal Movement.

The catalyst for the birth of this new movement was Rabbi Abraham Joshua Heschel (d. 1972), a Polish Jew who was born into a Hasidic family, but who also received modern university training. Heschel managed to flee Nazi-occupied Poland and settled in America in 1941 where he inspired scores of alienated American Jews to find their way back to the sources of Judaism in order to heal the atrocities of modernity, which culminated in the Holocaust. Heschel’s ecologically sensitive depth theology spoke of God’s glory as pervading nature, leading

humans to radical amazement and wonder, viewed humans as members of the cosmic community, and emphasized humility as the desired posture toward the natural world. Another product of Hasidism and a refugee from Nazi-occupied Europe was Zalman Schachter-Shalomi (b. 1924), who founded the Jewish Renewal Movement in the late 1960s. His creative reinterpretation of Judaism combined a “Gaia consciousness” with psychological interpretation of Lurianic kabbalah and New Age spirituality. Schachter-Shalomi urged a paradigm shift from monotheism to pantheism within Judaism but did not intend to revive neo-pagan pantheism. Instead, he offered contemporary Jews a new way to infuse Jewish life with rituals that envision a God who is an integral part of all human civilization. He articulated the view that all of humanity has a specific responsibility for that relationship. The rituals of the Jewish Renewal Movement are all contemporary variants of traditional Jewish practices (e.g., the pilgrimage festivals), but the movement inspires an ecologically based Jewish spirituality.

Shachter-Shalomi’s ideas were systematized into Jewish ecology by Arthur Green (b. 1941) who, under the influence of kabbalah, presented a holistic view of reality in which all existents are in some way an expression of God and are to some extent intrinsically related to each other. Green combines evolutionary theory (albeit without engaging its scientific details) with kabbalah and neo-Hasidism. He argues that the traditional doctrine of creation can no longer serve Jews in an age of science. Taking the evolutionary theory as descriptively true, Green reinterprets the biblical doctrine of creation that adopted the ontological schema of kabbalah. Offering a progressive interpretation of evolution as the emergence of ever more complex forms of life culminating in human beings, Green presented a holistic view of reality in which all existents are in some way an expression of God and are to some extent intrinsically related to each other. Contrary to those who hold that in Judaism nature per se is not sacred, Green wishes to obliterate the ontological gap between the Creator and the created. Instead, he adopts the monistic and

immanentist ontology of kabbalah and blurs the distinction between creation and revelation. The world and the Torah are both God’s self-disclosure and both are linguistic structures that require decoding, an act that humans can accomplish because they are created in the image of God. From the privileged position of the human, Green derives an ethics of responsibility toward all creatures that acknowledges the differences between diverse creatures while insisting on the need to defend the legitimate place in the world of even the weakest and most threatened of creatures. For Green, a Jewish ecological ethics must be a *torat hayim*, namely, a set of laws and instruction that truly enhances life.

Conclusion

Jewish-revealed legislation about nature constitutes a program for the preservation and conservation of a world that belongs ultimately to God. As God’s viceroys in the world, human beings carry out divine instructions because humans alone are endowed with the capacity to be responsible for others. The most distinctive feature of Jewish ecological thinking is the concept of responsibility and the ethics of care that flows from it, that is, care for the needy, the weak, the vulnerable, and the marginal. Jewish environmental ethics is decidedly anthropocentric, and it calls humans to action toward other humans and toward nonhuman creatures. Jewish environmental ethics of responsibility stands in conflict with any outlook that denies human uniqueness, be it deep ecology or Darwinism, especially in its distorted Nazi interpretation. Most distinctively, Jewish environmental ethics sees a causal link between moral failure and injustice in the social realm and environmental degradation. Greed, exploitation, and a lifestyle of material excesses ruin not only other humans but also the natural world. The Jewish tradition thus extols the merit of moderation and calls one to cultivate virtues such as modesty, humility, and self-restraint. These virtues and the actions that flow from them prevent the tendency for cruelty, including cruelty toward animals.

Although the Jewish tradition has many resources for the articulation of a distinctively Jewish approach to environmentalism, the science of ecology merely provides the information about the current ecological problems that the Jewish thinkers must address.

This is especially evident in the case of the environmental movement in Israel. In the Diaspora, Jewish ecological thinking is mainly theological and could be seen as a Jewish commitment not only for the preservation and conservation of nature created by God, but as a commitment to preservation of life itself. This commitment receives special significance after the Holocaust, since the Nazis were determined to annihilate the Jewish people as a particularly pernicious subhuman species. The most profound ecological response to the atrocities of the Holocaust was articulated by the German-Jewish philosopher Hans Jonas (d. 1993), who showed how to erase the gap between “is” and “ought” which in his view undergirded the instrumentalist attitude toward nature. For Jonas, life itself is endowed with moral significance rooted in the “needful freedom” of every organism. Jonas’s critique of technology inspired the Green movement in Europe, but his anti-utopian thought has made relatively little impact on Jewish intellectual life in the twentieth century.

As awareness of the ecological crisis becomes more prevalent among Jews, it is reasonable to expect that Jewish ecological thinking will become more prominent in the twenty-first century. But for this to happen, a new creative interplay between “science” and “religion” will have to come about as Jewish intellectuals become conversant in the science of ecology as well as in environmental philosophy and ethics, responding to them on the basis of the religious sources of Judaism.

[Business life](#); [Economy](#)

Economics is the study of people “as they live and move and think in the ordinary business of life” (Marshall 1890 [1949]: 12). Sociology is “a science which attempts the interpretative understanding of social action in order thereby to arrive at a causal explanation of its course and effects” (Weber 1922 [1947]: 88). Economics is production, consumption, distribution, and exchange. Sociology is meaningful interaction and recognized interdependence. Economics is

the activity. Sociology is the lens that makes sense of the activity. Economic sociology is the synthesis of the bedrock and the filter. It is a combination of making and getting on the one hand, socialization and culture on the other.

At the stage of production the organization hires inputs which have a pulse. Labor is supplied in the light of intrinsic and extrinsic motivation, Weber's work-ethic, and the socialist's class-based perception of injustice and exploitation. Capital is accumulated through gratification deferred and credit extended, normative rationality and unions contained. Land is the property of a third estate, at once return-seeking and history-dominated. Rent in a modern economy is a form of profit. Rent in a traditional economy is how the hereditary aristocracy defines its social space.

At the stage of consumption it is the lesson of institutional comparison that commodities are not just the disembedded bearers of individual utility but also vocal modes of self-presentation and identification (Goffman 1959). As signifiers they confirm that the user is cognizant of the code and conforms to the pattern: "A man would be ridiculous who should appear in public with a suit of clothes quite different from those which are commonly worn" (Smith 1759 [1966]: 284). As trophies they are proof that the contender has played a zero-sum game and defeated his second-best rivals: "In order to gain and to hold the esteem of men it is not sufficient merely to possess wealth or power. The wealth or power must be put in evidence" (Veblen 1899 [1970]: 42). In some societies, esteem is earned through political leadership or acknowledged wisdom. In other societies, standing is purchased through earning and spending: "I am not *ugly*, for the effect of *ugliness* – its deterrent power – is nullified by money" (Marx 1844 [1973]: 167).

That is why the distribution of income and wealth is so important. More spending means more respect. More property means more power. Ownership creates a master-servant relationship which can be perceived as demeaning and undeserved. Alienated lumps of labor might prefer consultative producer-cooperatives in which all surplus value reverts to the productive. The liberal society might find the inheritance of

capital at variance with the free market criterion of achieved status. Sometimes, however, the intergenerational transmission of advantage will be seen in a more attractive light. Sentimental social conservatives will define it as the embodiment of the unbreakable links of kinship and the perpetuation of a going concern.

At the stage of exchange there is the agreed-upon *quid pro quo*. Exchange is theft unless the contract is supported by non-contractual consensus: "There is no truly moral force save that involved in attachment to a group" (Durkheim 1925 [1961]: 87). The protection of title is ensured both by widely diffused norms and by the monopoly of legitimate authority that is exercised by the judges and the politicians.

Exchange presupposes the socially validated standard of reciprocity. This may build upon the convention-driven exchange of Malinowski's *kula* (Malinowski 1922) that is handed on through the non-mercantile custom of Christmas presents and the multi-party social exchange of integrated blood donors who confidently stake their survival on an uninsurable return gift: "In not asking for or expecting any payment of money these donors signified their belief in the willingness of other men to act altruistically in the future" (Titmuss 1970 [1973]: 269). Alternatively, exchange may build upon the neoclassical economist's rational calculation of costs and benefits in a resource-scarce world where optimizing catallactics has the missionary function of satisfying discrete and multiple desires: "It gives people what they want instead of what a particular group thinks they ought to want" (Friedman 1962: 15). Exchange is broader than utility and profit alone.

Exchange is often defended with the argument that the free market is anonymous and impartial. An alternative perspective is that economic decentralization works well precisely because of replicated interactions, return business, reputational capital, and embedded conventions that save on the transaction costs of collecting information and monitoring shirkers. Putnam, writing about who-knows-whom, observes that "social networks allow trust to become transitive and spread: I trust you, because I trust her and she

assures me that she trusts you” (Putnam 1993: 169). Granovetter found that as many as 56% of jobs were secured through personal contacts external to the firm (Granovetter 1974 [1995]: 11): “Economic action (like all action) is socially situated, and cannot be explained by individual motives alone; it is embedded in ongoing networks of personal relations rather than carried out by atomized actors” (Granovetter 1992 [1996]: 270). It is Chinese *guanxi*, Soviet *blat*, and Japanese sequential contracting that is the ultimate guarantor of truth-telling and the categorical imperative. A businessman does not cheat his wife’s brother or a new immigrant from the village where his kinsfolk live. The allocation of resources in this way becomes a path-dependent history of remembered relationships.

Economics is production, consumption, distribution, and exchange. Yet, it is also political economy, situated at the confluence of market homeostasis and the visible hand. The State coordinates entitlements and regulates spillovers. Thus, Pigou maintained that where the marginal social benefit differed from the marginal private benefit, the missing market necessitates corrective action through taxes and subsidies (Pigou 1920 [1932]). Coase argued the opposite, that only the factored-down one-off is in a position to buy and sell an externality precisely because only the isolated utility-seeker can know what will make him feel better off in his own estimation (Coase 1937 [1988]). Ostrom for her own part assigns pride of place to social infrastructure (Ostrom 1990). Tribal loyalties and Tönnies’s *Gemeinschaft* (Tönnies 1887 [2001]) ensure that Pigou’s intervention and Coase’s privatization will not be required to prevent the overgrazing of the commons. Affect and belonging will be enough.

Fred Hirsch writes that “the controllers usually have a large handicap of relevant information. Only I can see everywhere I litter” (Hirsch 1977: 150). He then observes that socialized men and women will be led as if by a guilty conscience to act out the drama for which their evolving society has kindly scripted the scenario. One by-product is voluntary action and nongovernmental organizations. Standing between market and State are environmental

lobbies that speak for the whales, and welfarist pressures that speak for the old. Civil society is not supply and demand and it is not the *diktat* from the top. It is, nonetheless, an economically relevant constituency which is incorporated with great difficulty into Spencer’s Manichean *The Man Versus the State* (Spencer 1884).

Yet globalization is a challenge to a single country’s *conscience collective*. Internationalization could mean the emergence of a worldwide consensus even as it could mean the babel of *anomie*. Local knowledge is becoming a nonlocal thing. Increasing integration takes Keynesian demand-management and the social welfare democracy beyond the territoriality of a Whitehall or a Washington alone. As problems become shared, so shared solutions emerge in the form of the European Union, the European Central Bank, the World Health Organization, and the multinational conglomerate answerable to no polity but the color of money. A multi-societal society is inevitable. In evaluating the new skein of affiliation, the cross-disciplinary subject-area of economic sociology will have an important role to play.

[Buddhist doctrine](#)

Education as a term does not exist in early Buddhist scriptures, i.e., the canonical texts of the Pali-Canon. Similar to Plato's Politeia – a political script containing the first systematic theory of education in the Occident – early Buddhist writings expound an educational philosophy and methodology embedded in its philosophical or spiritual content. This becomes obvious when Buddhist texts are screened on behalf of the three main quests of educational theory:

1. The anthropological: What is a human being?
2. The teleological: What is a human being supposed to be or become?
3. The methodological: How can education help the individual to achieve its teleological purpose? (Böhm 1994).

In the following, Buddhist tenets regarding these aspects will be outlined in relation to their educational implications.

Anthropology

Human beings are, according to early Buddhist philosophy, beings among seven other categories of beings, i.e., animals within 31 planes of existence (U Ba Khin 1951). Contrary to other forms of existences, humans are regarded privileged, as due to their mental capacity and the ability of self-awareness, progress and development are easier to accomplish. Furthermore, since human beings experience happiness and pain, the urge to emerge from suffering functions as a driving force, supporting a progressive attitude.

Human beings are born in the plane of *Kāma Loka*, a sensual world with mind and matter. Here, matter comprises of eight to ten qualities that constitute the whole of the material world. The basic components are extension, cohesion, kinetic energy, motion, and space. They can be accompanied by subsidiaries like color, odor, taste, nutritive essence, consciousness, and sex. The smallest unit of matter is called *kalapa*. It is only when a minimum of eight nature elements (four basic components accompanied by subsidiaries) are combined that a *kalapa* is formed. This constitutes mass in the description of Buddhist philosophy. These *kalapas* are in a state of perpetual change or flux. They are merely a stream of energies. The body of a human being is not an entity in Buddhist doctrine but a continuum of matter and life force coexisting. Through meditation, activating the introspective qualities, a human being can develop the ability to perceive his own body and external material objects as mere energy and vibration.

The mental aspects of human beings are divided in 121 categories which are explained in detail in the *Abhidharma*, the scholastic manuals of Buddhism (Bodhi 2000). On a generalized level, they are divided into four main categories: consciousness, feeling, perception, and volitional

energies. Human beings are, according to Buddhist scriptures, a continuum of these material and mental aspects coexisting. In the course of dependent origination and the law of cause and effect, the main cause of human beings coming into existence is determined by ignorance (Ledi 1999). Being the first aspect in the chain of dependent origination, it is also the central issue of Buddhist teleology.

Teleology

The teleological aspect of what humans are ideally supposed to become is expressed in Buddhist philosophy. The following conversation attributed to the Buddha and his chief disciple Sariputta, exemplifies this teleology.

Sariputta: There is talk of great human beings, o Lord. What then is meant by a great human being, o Lord?

The Buddha: Great human beings are characterized by a liberated mind.

Without a liberated mind, there is no great human being. (Nyanaponika 2000)

Liberation of mind is defined as the liberation from ignorance and illusion. Non-liberated beings are, according to Buddhist philosophy, ignorant of their true nature, of the true nature of mind and matter phenomena, and of the ultimate truth of Nirvana (see below). Based on this ignorance, human beings generate suffering by their acts of body, speech and mind. Ignorance, wrong view, and illusive perception are inherent in every non-liberated human being. To liberate oneself from this illusion, therefore, becomes the main purpose of human existence and life.

With the dissolution of ignorance, Nirvana is realized. Whereas all things in the realm of mind and matter are conditioned, Nirvana is not. It is, according to Buddhism, the only ultimate reality, accessible not by annihilation of physical existence but by the purity of one's mind. Nirvana is described as "the Unformed, the Unconditioned, the End, the Truth, the Other Shore, the Subtle, the Everlasting, the Invisible, the Undiversified, Peace, the Deathless, the Blessed, Safety, the

Wonderful, the Marvelous, Purity, Freedom, the Island, the Refuge, the Beyond” (Amaro and Passano 2009; Feer 1898).

Awakening to the reality of Nirvana is, according to the Buddhist doctrine, the ultimate goal of human life and the successive liberation from illusion the highest and ultimate form of education.

Methodology

Buddhist philosophy consists not only of an anthropology and teleology but also of a highly differentiated methodology to accomplish the teleological goal. This methodology is laid down in a threefold training of virtue, serenity of mind, and insight.

Virtue

Virtue is regarded as the foundation for mental development and comprises all actions of body, speech and mind. Actions are virtuous when performed on the basis of non-greed, non-aversion, and non-delusion leading to contentment, peace of mind, and happiness. Actions based on craving, aversion, and delusion, on the other hand, have the seed of suffering inherent in them and are therefore opposed to Buddhist teleology. Moreover, Buddhism emphasizes whoever performs unvirtuous actions is going to be his or her first victim of this deed: “It is impossible to commit an unwholesome action – to insult, kill, steal or rape – without generating great agitation in the mind, great craving and aversion. This moment of craving and aversion brings unhappiness. When we commit unwholesome actions we experience the hell-fire of craving and aversion. When we perform wholesome actions we experience the heaven of inner peace. Therefore it is not only for the benefit of others but for our own benefit, to avoid harm to ourselves that we abstain from unwholesome words and deeds (Hart 1991).”

Serenity of Mind

Serenity of mind is the second aspect of the threefold training. Since, according to Buddhist

philosophy, insight cannot be accomplished unless the mind has the capacity to penetrate the illusive apparent level of appearance, mental training is necessary to acquire such sharpness and clear vision. Buddhist instructions consist of 40 methods to help the mind to lose its unstable, unconcentrated, flickery, conditioned, and highly associative nature and to gain the advantage of a serene mind. The serene mind is the prerequisite for insight, comparable to the still surface of a pond allowing the observer to view its base.

Insight

Insight as the final goal of Buddhist practice eliminates ignorance, illusionary view, and perception. With the realization of the true nature of mind and matter, its causes and effects, relations, and the final realization of Nirvana, distinct of all conditioned phenomena as is the case in the realm of mind and matter, inconceivable happiness arises. Therefore, the educational goal of insight is simultaneously accompanied by happiness. Insight meditation techniques are summarized in one of the most famous Buddhist scriptures: The satipatthāna sutra or the discourse on the four foundations of mindfulness. These four foundations incorporate meditative practices on the body, on feelings and sensations, on the mental and its concomitants, and on phenomena as such.

In recent years, there have been growing attempts to establish mindfulness practices within the educational system and research in the field of mindfulness with youth. Although the research is in its infant stage, results are promising and suggest mindfulness as a meaningful tool in the course of education. So far, results suggest an improvement of attention, academic performance, and social behavior. Research also points toward a reduction of stress, anxiety, and fear and an increase in emotional balance.

Description

For a Definition

The sociology of education, or educational sociology, focuses on the relationship between society and education. As all the applied sociologies the sociology of education can be specifically understood for its field of study, which regards the educational processes referred to particular societies, institutions and educational models.

Thus, the sociology of education requires different disciplines with connected different methodologies and tools for a grounded understanding of the society-education relationship. The sociology of education is part of the society of knowing it as that particular field of research aiming at studying and understanding the processes of socialization with particular reference to family, mass media, educational institutions, and teaching communities (such as school, university, and religion). It is possible to summarize the phases of study of sociology of education as follows: definition of society and community, determination of the particular context of education, relationship between education and society, social interaction, and study of education as social science (Ottawa [1998](#)).

Sociology and Science of Education Between History and Epistemology

The attention of sociology for education goes back to the end of twenty-first century, when Edward Alsworth Ross in 1898 dedicated the first course of sociology for teachers at the Stanford University, where 3 years later a course explicitly called *Sociology of education* was taken by David Snedden. Other courses specifically focused on the sociological study of education have been organized during the first decade of twentieth century at the University of Virginia and at the Teachers College of the Columbia University of New York (Brookover [1955](#)). Anyway the official birth of the sociology of education is usually referred to the publication of *An introduction to education sociology* by W.R. Smith in [1917](#). This book was a new starting point of the theory and the practice in education for a society complaining the growing neglect of educational practices.

Subsequently the *National Society for the Study of Education Sociology* was founded, and from 1925 it was a landmark for the studies in the field. In 1927 starts the publication of *The Journal of Educational Sociology*. The Editorial (pp. II–IV) of the volume number 1 (1927), provocatively asking if there is a specific aim of the new journal, among other things stated: “The editors and backers of this magazine answer

this question in the affirmative. There are several reasons for this answer. First, while there are a number of magazines that accept articles devoted to sociology in its application to education, no one magazine is devoted exclusively to that field. The sociological aspect of education cannot be properly represented without the emphasis that will come from a journal devoted to educational sociology. Second, sociology is a new science in the process of development, and already there is a body of material, essential to educational reconstruction and practice, which is not available to the educator..." (ib., II).

A determining point for the field is the book *Éducation et sociologie* of É. Durkheim. The following definition is very famous: "The education is the action exercised by adult generations on those who are not yet mature for the social life" (Durkheim 1922). The French sociologist defines the following aim of the education: "at the selfish and asocial being who comes into the world be superimposed another one, who is able to live a moral and social life" (Durkheim 1922). The social function of education is a matter of fact, because the society guarantees itself and above all its conservation exactly through the *process of socialization of education*.

In Europe, through the twentieth century, this approach to education does not have many supporters. In fact, in Germany, Italy, and England, there are few and occasional publications until the 1960s, even if there is a specific attention to the education processes in the books of authors like Comte, Marx, Scheler, Mannheim, and Dewey.

Through all the last century in the United States there is a lively debate (particularly regarding the "educational sociology") and a significant scientific production (Peters 1924). In a country with a flourishing educational tradition, as it was Italy, the socio-educational researches started in the universities only at the beginning of 1960s, with the national meeting *La scuola e la società italiana in trasformazione* (*The school and the Italian society in transformation*), which stressed the desirable relationship between sociology,

pedagogy, and social psychology with different multidisciplinary approaches (Ardigò 1966).

Through the "short century" the sociological study of educational processes has become even more important (Hoyme 1961), as shows the work of Paul Freire, according to whom the education alone is not able to transform the society, but the education is the only element which can help society in its process of improving. In this perspective, education plays a fundamental role, as a practice of freedom from the oppression (Freire 1970). Freire, using a Marxist approach for the critique of contemporary society, between 1960s and 1970s underlines some relevant problems regarding the relationship between socialization of knowledge and social change, starting from a deep analysis of the illiteracy rate which divided the Brazil. From the research started by Freire emerges a social lecture of education and of its fundamental role in the definition of individual and social personality.

It is progressively defined as a *social function of education*, as described by Maurice Blondel with his *philosophy of action*. According to the French philosopher, all emerges from action, because from the social point of view nothing is really "static". The society is fundamentally grounded on human relationship that is by definition dynamic, so driven by the dynamic relationship between persons, even in the commercial or industrial field (e.g., the development of social psychology and the marketing studies on the likings of commercialized products or of products to commercialize). According to Blondel every experience is *Erlebnis*, that is a "lived experience". The voluntary action is an action aimed at building the society. The education is one of its fundamental parts: "the action is for society, and we are tied one to another only through action. And as one is not first a man and then that particular man, so the society does not exist without being that determined society" (Blondel 1893).

Through the time the educational sociology is better understood as study of the experience of the teaching and learning processes.

New aspects and new developments emerge from the recent research in Anglophone area and even in Italy, for instance, the study of the economy's influence on training processes (Brown et al. 2008; Ribolzi 2012). Within the worldwide economic crisis, the speculators often use psychological factors in order to obtain big advantages, at the expense of the States and of the individual investors and citizens. As if it were a sort of battle fought on Wall Street as in Milan or Berlin, using the weapons of economic indicators.

This situation is a cause of uncertainty for the individual existences and for the whole society that are on the chasm of the existential liquidity (as an example Bauman 2000, 2012). Obviously this confirms the "prophetic" role played by education in the transformation of social aims, when society is not able to guarantee the right flourishing of every citizen. Even the religious leaders stress the danger of this situation and advocate a new social model not grounded on the gains, but on the individual good, as the Christian churches (Gutschera et al. 2003) and the last popes do. In the personalist perspective of John Paul II, the education plays a fundamental role in order to develop new life-styles (Encyclical Letter, *Centesimus annus*, 1 May 1991, n. 36).

Globalization, Education, and Project of Life: Toward a New Research

In the educational process, the environment plays a fundamental role, not for determining, but for promoting the processes of growth. The environment, both human and natural, interact with educational processes that are deeply tied to different natural, cultural, and social contexts. In this way, a new role for school and educational processes emerges: They must develop an even more strong coordination with the processes of socialization. This is a consequence, among other things, of the *globalization* even in the field of instruction and knowledge, which has redefined the aims of educational sciences, not only for the economies and the markets (Gallino 2003). Education, in this new scenario, is defined as

proposal and project of life, assumed as a phenomenon which goes on for all the life, going over the spatiotemporal limits of the school and the professional training (Torres and Mitchell 1998; Scanagatta 2002).

Because of the richness and the variety of potential educational and training "objects", the individual is almost obliged to select. He has to responsibly build a personal project of using an ever more available market of symbolic objects. At the core of the modern socialization is the subject, able to manage with growing autonomy the different available training resources, exactly because of the mutual dependence and relationship between educational experience and society (Blyth 2002; Colbati 2006). Saying it in a different way, the training society, that is the school, has to take into account the social community and interact with the different contexts and factors. This model requires that the educational sociology not only observes, but also critically analyzes the effects on the social life that such an educational relationship has.

Thus, it seems fundamental to hope an ever deeper relationship between *paideia* (learning, training, and education) and freedom, quality of life and existential planning (Cambi 2008). It is possible to define an eco-socio-organization of the learning processes which can really stress the resources of the educational environment (in the sense of nature and nurture) connected to the broader social contexts, in order to underline the relationship between learning and development of the person (autopoiesis) (Mangano and Michelin Salomon 1998).

The contemporary crisis of educational systems, of institutions (as school and university), and of family raises the necessity to deeply, but even dramatically reflect on the future of the relationship between society and education. To better understand the contemporary processes of socialization the following statement of Dewey is of great help: "If there is especial need of educational reconstruction at the present time, and if this need makes urgent a reconsideration of the basic ideas of traditional philosophic systems, it is because of the

thoroughgoing change in social life accompanying the advance of science, the industrial revolution, and the development of democracy. Such practical changes cannot take place without demanding an educational re-formation to meet them, and without leading men to ask what revisions they require of the ideas and ideals which are inherited from older and unlike cultures” (Dewey 1930, 386).

EEG (Electroencephalogram)

Heiko J. Luhmann

Department of Physiology, Institute of Physiology and Pathophysiology, University Medical Center of the Johannes Gutenberg University of Mainz, Mainz, Germany

An EEG measures the electrical activity produced by the brain (mostly the outer mantle of the brain, the so-called cerebral cortex), which is recorded with electrodes placed on the scalp. Whenever the brain shows large-scale synchronized neuronal activity, as during sleep, rhythms

of certain frequency and amplitude can be observed in the EEG. The EEG is used to define states of awareness, sleep states, and the state of brain death (isoelectric or flat-line EEG).

Eight Fold Path

Dustin Byrd
Olivet College, Olivet, MI, USA

Developed by the Siddhartha Gautama, the Eight Fold Path is the way toward the liberation of the individual from his attachments and delusions. The ultimate goal is the cessation of suffering. They are broken up into three categories. (1) Wisdom, comprised of Right View and Right Intention, (2) Ethical Conduct, comprised of Right Speech, Right Action, Right Livelihood, and (3) Concentration, comprised of Right Effort, Right Mindfulness, and Right Concentration.

Description

Electrodynamics

Electrodynamics (or electromagnetism) is a part of physics dealing with the interaction forces between electric charges and currents, nature of electric and magnetic fields, and electromagnetic wave radiation and propagation, as well as the interaction of electromagnetic waves with matter. It involves two fundamental concepts – electrical charge and electromagnetic field. It also involves additional derivative concepts which are related either to the characterization of the sources of the field or to the characterization of the field and its manifestations. Both the fundamental and the derivative concepts are characterized by two types of quantities: (1) local quantities, i.e., related to a particular given point in space, and (2) integral quantities, i.e., related to a given region in space. In addition, both, the local and the integral quantities, have their own specifics in two particular cases – in vacuum and in matter.

The Concept of Electrical Charge

Experiments have shown that the fundamental building blocks of nature, the elementary particles such as electrons, neutrons, and protons, could be electrically neutral or could be characterized by two different types of electrical charges – positive and negative. Like charges repel one another, while opposite charges attract. The interaction between electrical charges can be

quantitatively described by means of Coulomb's law (Charles Coulomb, 1736–1806): The electrical force between two charges at rest is directly proportional to the product of the charges and inversely proportional to the square of the distance between them. Coulomb's law describes the force of interaction between charges at rest, i.e., it works within the realm of electrostatics. The ability to measure electrical charges made it possible to realize that they are discrete in nature and that there is a minimum quantity of electrical charge – the charge of the electron. The absolute measured value of any electrically charged body is proportional to the absolute value of the electrical charge of the electron. Finite physical objects are usually electrically neutral since they contain equal amounts of positive and negative elementary particles as part of their internal structure. The excess of one particular type of elementary particles (positively or negatively charged) leads to the possibility for finite physical objects to possess an electrical charge in one of the two possible types. This is due to the fact that electrical charges are subject to an "addition rule" that follows the rules of addition of algebraic numbers. When summing charge, positive charges are represented as positive numbers and negative charges as negative numbers. However, there is a *charge conservation law* stating that in any closed system, the total electric charge remains constant. The total electrical charge of a physical object is an example of integral characteristic – it characterizes the electrical properties of the object as a whole and does not provide information about the distribution of its constituent elementary particle charge within the body. An example of local characteristic is the electrical charge volume density which characterizes the electrical charge within unit volume at a given point in space. The distinction between integral and local characteristics of electrical charges enables a dual possibility for the specific form of the quantitative physical laws describing them. The laws of electricity and magnetism, and of electrodynamics in general, can be expressed in both integral and differential forms. However, the integral form tends to be more general since it could be applied to arbitrary types of electrical

charges and currents, while the differential form has some additional requirements such as the continuity of the spatial distribution of the charges. Electrical charges are a relativistically invariant physical quantity – they do not change when moving from one coordinate system frame of reference to another. This property is fundamental for the inherent relativistic nature of electrodynamics where the possibility to study electromagnetic phenomena in different coordinate system frames of reference is a key.

It is important to point out that by saying that the concept of electrical charge is a fundamental concept, we mean that it cannot be described in simpler, more basic concepts. In the words of Eugene Hecht: "We know it by what it does and not by what it is – if you like, it is what it does, and that's that" (Hecht 2000, p. 610). We therefore do not know what an electrical charge is in its essence. This statement is equally valid for both classical and quantum electrodynamics. It is also important to point out that when we use the term "electrical charge" we could mean two different things: (1) the physical quantity describing the properties of electrically charged bodies or (2) the body or the particle possessing the electrical charge. Mixing both concepts together does not usually lead to confusion; however, it is important to keep this distinction in mind since it points out the fact that it is always a specific particle or object that manifests the properties of an electrical charge and that these properties are just one type out of several others, e.g., the gravitational ones (characterized by the mass of a particle or an object).

The Electromagnetic Field Concept

The second fundamental concept in electrodynamics is the concept of electromagnetic field which provides a unified picture of the electric and magnetic phenomena. In the case of electrostatic phenomena, we can focus our discussion on the electric field alone. According to Coulomb's law, a charge Q_1 exerts a force on a second charge Q_2 , and vice versa. Coulomb's law however does not explain how this force is transmitted through empty space. In order to answer this question, physicists in the nineteenth century

developed the concept of *electric field*. A charged particle, such as an electron, interacts with other charged particles by creating a web of interaction around itself that extends out into space. We say that one charge creates an electric field in space and another charge immersed in that field interacts directly with it, and vice versa. The field that surrounds an electrical charge is part of it. For example, the total energy of an isolated electron at rest equals its internal energy ($E = mc^2$, where m is its mass) plus the energy of its field. Two different electrons interact through their respective fields. The total energy of the system including the two electrons is equal to the sum of the energies of its parts, i.e., the two electrons and their fields. It is this total energy of the system that is subject to the energy conservation law and that is being conserved during the interaction.

The picture so far seems to be quite straightforward, but it raises (and has raised in the past) some very interesting questions. One of the most interesting of them is why do we need the field concept at all. The answer is that we need – in order to deal with the explanation of the “action at a distance” and the principle of “locality” – the expectation that effects must be colocated with their causes, both in space and in time. One electron causes another, second, electron located at some distance away to experience a certain force. This force seems to have no cause located any nearer to the second electron. It seems, therefore, that there is no visible local cause for the force experienced by the second electron. The introduction of the field concept enabled the description of the interactions between electrically charged bodies in a way that satisfies spatiotemporal locality and explains the action at a distance – the electric force on each of the charged bodies at a given moment in time is caused by the electrical field at its location. One of the key challenges in such an approach comes from the fact that we are dealing with a macroscopic but, at the same time, invisible physical reality – the field is invisible but it becomes visible by its effects. Its energy is manifested by the work done by the electrical field force to move the charge away at a given distance.

This simple exposition of field theory shows that the concepts of energy and field are inherently interrelated. “A field is a region in space in which any point can be characterized by a set of numbers. These may be scalars, for example energy, or vectors, for example forces, and so we may have scalar or vector fields. Energy is a scalar, and as we shall see, it becomes the basic ‘substance’ of field physics, as matter was the basic ‘substance’ of Newtonian physics.” “It is so because the field is characterized by the presence of energy. . . . A field is nothing more than a spatial distribution of energy which varies with time. Energy has thus been freed from its dependence upon physical vehicles such as particles; it has achieved the status of independent scientific existence” (Theobald 1966, p. 50).

The inherent relationship between the energy and field concepts makes the questions about their existence somehow interchangeable. It is interesting to discover that in physics the existence of the physical reality behind the concepts of energy and field might be questioned. The answers of many eminent physicists to similar questions are ambivalent. For example, according to American physicist and philosopher of science Percy Bridgman (1882–1961), 1946 Nobel Laureate in Physics: “The reality of the field is self-consciously inculcated in our elementary teaching, often with considerable difficulty for the student. This view is usually credited to Faraday and is considered the most fundamental concept of all modern electrical theory. Yet in spite of this I believe that a critical examination will show that the ascription of physical reality to the electric field is entirely without justification. I cannot find a single physical phenomenon or a single physical operation by which evidence of the existence of the field may be obtained independent of the operations which entered into the definition. The only physical evidence we ever have of the existence of a field is obtained by going there with an electric charge and observing the action on the charge . . . , which is precisely the operation of the definition The electromagnetic field itself is an invention and is never subject to direct observation. What we observe are material bodies with or without charges

(including eventually in this category electrons), their positions, motions, and the forces to which they are subject” (Lange 2002, p. 41). Such statement may seem strange, but there is one aspect in which it is not so trivial. In the case of the system of two electrons considered above, does the field of the first electron exist when the second one is not present, i.e., independently of it, or its presence is *enabled* by the proximity of the second electron? This question may be considered as being not about the reality of the field in general but about its reality independently of the second electron. Such question, however, does not seem to fall within the scope of interest of the majority of physicists whose reasoning functions under the premises of operationism – the view that the meaning of every scientific term must be specifiable by identifying a definite testing operation that provides a criterion for its application. This entails that for most physicists, “the whole of physics is about operations, chiefly measurements and computations, rather than about nature” (Bunge 1973, p. 1). Such an approach to the definition of a concept is called operational. The operationist attitude to scientific concepts has a long history and, as we have seen, tends to put aside questions of whether the object of the definition exists in reality or not.

Electric fields have a real physical existence and are not just theoretical constructs invented by physicists to get around the problem of the transmission of electrostatic forces through vacuum. The certainty about the real existence of the fields comes exactly from the fact that they possess energy and that it is actually possible to convert this energy into heat or work, and vice versa. The ambiguity of the question about the realism of the electric field seems to appear due to the fact that when we discuss the reality of the fields, we are silently focusing on static fields, i.e., the electric fields of electrical charges that do not move in time and space. Electrodynamics deals with dynamic, i.e., changing in time, electric, and magnetic fields. When an electrical charge undergoes acceleration, a portion of its field “detaches” itself and travels off at the speed of light, carrying with it energy. This is what we call electromagnetic radiation and its reality is

impossible to question. “Its existence invites (if not *compels*) us to regard the fields as independent dynamical entities in their own right, every bit as ‘real’ as atoms or baseballs. . . . But it takes a charge to *produce* an electromagnetic field and a charge to *detect* one . . .” (Griffiths 1999, p. xiv). Thus, taking into account the dynamic nature of the electromagnetic fields resolves the ontological ambiguities associated with their existence.

Electromagnetic Wave Theory

The rigorous electromagnetic theory was developed over the course of the nineteenth century by James Clerk Maxwell (1831–1879) who used his mathematical skills to build on the physical insights and the experimental genius of Michael Faraday (1791–1867) in unifying all known electromagnetic phenomena into a single set of equations – the Maxwell’s equations. Maxwell’s work on electromagnetism has been rightly considered as the second great unification in physics, the first one being the universal theory of gravitation developed by Isaac Newton (1643–1727). Maxwell’s equations can be briefly summarized as follows. The first equation describes how electric charges generate electric fields. It is also known as Gauss’ law and states that the amount of electric field coming out of any closed surface (the electric flux) is proportional to the total charge enclosed by the surface. In short, it is related to the experimental fact that electrical charges are the sources of electrical fields. The second equation is the magnetic equivalent of Gauss’ law and points to the fact that there are no experimentally observed magnetic monopoles, i.e., the amount of the magnetic field coming out of any closed surface (the magnetic flux) is equal to zero. The third equation is Faraday’s law. This equation describes mathematically how changing magnetic fields generate electric fields. The fourth, and final, equation is Ampère’s law describing how electric currents and changing electric fields generate magnetic fields. With these four elegant equations, Maxwell showed that electricity and magnetism were simply aspects of one single electromagnetic force.

Optics

One of the most important results of Maxwell's work was that the electromagnetic field predicted by the theory turned out to propagate at a speed equal to the speed of light as experimentally measured at that time. Maxwell demonstrated that all phenomena involving electricity, magnetism, and light could be explained by means of the concept of electromagnetic field. It was realized that the whole spectrum of radiations, radio waves, infrared, visible, ultraviolet, X-rays, and g-rays, were all electromagnetic radiations moving at the speed of light. Since then, it became clear that optical phenomena are just electromagnetic wave phenomena that could be characterized within a specific frequency range which happens to be visibly perceptible by the human eye and highly relevant for all living organisms. Optics has developed through the ages as an independent part of physics with its own theoretical specifics and practical applications (Hecht 2002). However, the most accurate language of optics is the rigorous language of the theory of electromagnetism (Born and Wolf 1999). In most of the cases, optics deals with the propagation of light through transparent media and its interaction with mirrors, lenses, slits, etc. Optical effects can be divided into two broad classes: (1) effects that can be explained without reference to the fact that light is fundamentally a wave phenomenon, and (2) effects that can only be explained on the basis that light is a wave phenomenon. Let us, for the moment, consider the former class of effects. It might seem somewhat surprising that any optical effects at all can be accounted for without reference to waves. After all, as we have already seen, light really is an electromagnetic wave phenomenon. It turns out, however, that wave effects are only crucially important when the wavelength of the wave is either comparable to, or much larger than, the size of the objects with which it interacts (Hecht 2002; Born and Wolf 1999). When the wavelength of the wave becomes much smaller than the size of the objects with which it interacts, then the interactions can be accounted for in a very simple geometrically intuitive way. Since the wavelengths of the visible light are only of order a micron, it is very easy

to find situations in which its wavelength is very much smaller than the size of the objects with which it interacts. Thus, a waveless approach to optics, which is usually called geometrical optics approximation, has a very wide range of applications. In geometric optics, light propagation is treated as light rays, emanating from a source, which propagate through transparent media. There are three laws of geometrical optics. The first law is the law of rectilinear propagation, which states that light rays propagate in straight lines through homogeneous transparent media. The second law is the law of reflection, which governs the interaction of light rays with conducting surfaces (e.g., metallic mirrors). The third law is the law of refraction, which predicts the behavior of light rays as they traverse sharp boundaries between two different transparent media (e.g., air and glass).

Geometric optics has proven to be a highly successful theory. Its most important applications focus on describing and explaining the operation of commonly used optical instruments: eyeglasses, cameras, telescopes, microscopes, etc. Although geometric optics does not make any explicit assumption about the nature of light, it tends to suggest that light consists of a stream of massless particles. The wave theory of light, which developed in the first half of the nineteenth century, initially encountered significant resistance since scientists thought that, if it were a wave, light should have manifested its wave nature through such phenomena as interference and diffraction – phenomena in which waves do not travel in straight lines and would not cast straight, sharp shadows, the same as water waves do. Later on, however, with the works of Christian Huygens (1629–1695) and Thomas Young (1773–1829), the wave theory of light emerged and was established as an alternative approach to the understanding of optical phenomena. Young's double-slit interference experiment has clearly demonstrated the wave nature of light and became the model for other revolutionary experiments in modern physics demonstrating the complementarity of the particle and wave properties of elementary particles within the context of the emerging quantum physics.

The Photon: The Optical Quantum of Energy and Action

The idea of the quantum of energy was introduced as a kind of energetic atomism, in which energy could not be divided into arbitrarily small amounts but existed as discrete, tiny packets. In its origins, the introduction of the concept of energy quantization was driven by deeply practical reasons. In 1900, it allowed German physicist Max Planck (1858–1947) to create an adequate mathematical model of the so-called black-body radiation. Planck worked with careful experimental measurements of the actual energy distribution trying to develop a correct theoretical model to describe it. Eventually, he found out that he could do that only if he assumed that the emitted energy could change only in jumps, from one energy level to the next. This assumption in Planck's model violated the usual way of thinking about energy – as a quantity that could vary smoothly, increasing or decreasing gradually, rather than being confined to stepwise change. Planck called these discrete energy changes “quanta” of energy. Very soon, other physicists began to see the more universal meaning in Planck's idea. In a paper of 1905, on the photoelectric effect, Albert Einstein (1879–1955) argued that light itself should not be understood simply as wave motion but should also be understood in terms of light quanta – massless packets of energy that were later to be called “photons.” The energy of a single photon E was found to be proportional to the light's frequency ν by means of a universal constant h : $E = h\nu$. The constant h was first derived by Planck and, therefore, known as Planck's constant or the “quantum of action.” Soon after the emergence of the photon, the idea of the quantum nature of energy was extensively infiltrated into microphysics. In 1913, Danish physicist Niels Bohr (1885–1962) opened up a critically important new arena for the use of the quantum concept – atomic spectra. It was the exploration of this arena that led to the emergence of the new or *quantum physics*. Bohr adopted Planck's quantum concept to study the internal structure of atoms in a way that was “in obvious contrast to the ordinary ideas of electrodynamics but appeared to be necessary to account for some

of the unexplained experimental facts” (Dear 2006, p. 144). He started with the commonly accepted “solar system” model of the atom wherein negatively charged electrons orbit around the central positively charged nucleus like planets. “The size of an electron's orbit corresponded to the orbit's energy, and Bohr postulated that the only orbits permitted to such electrons were those whose energy corresponded to discrete, quantized levels – not just any amount of energy, or orbit, was allowed by his model. There were levels, or steps, of orbital energy that the electrons could occupy. Bohr called them ‘stationary states.’ The only changes in orbital levels that an electron could undergo were the ones in which it shifted, in a discrete jump, from one stationary state to another” (Dear 2006, p. 144). Assuming the discrete nature of these changes allowed Bohr to interpret some experimental results that had been known for nearly 30 years. These results concerned the radiation emitted by hydrogen atoms when excited by heat. When the radiation was separated out according to frequency by a spectroscope, the spectrum showed a series of discrete bright lines that were uniquely related to the specific internal structure of the atom. Niels Bohr's achievement consists of the demonstration that the energetic manifestations of light quanta could be identified with the composition of atoms and the structure of matter in general. The dynamic structure of matter is manifested and could be known by the particular mode by which the smallest quantities of energy are presented to the observer. Or, in the poetical theological language of Christos Yannaras, “That means that the hypostasis of matter itself is energy, that matter contains the constituents of light, that light is the ideal matter” (Yannaras 1998, p. 39).

A Relativistic Quantum Theory of Electrodynamics

Unlike Newtonian mechanics, classical electrodynamics is a relativistic theory, i.e., there are no fundamental problems to incorporate in it the effects of special theory of relativity – the explanation of electromagnetic phenomena that involve changes happening at a speed comparable to the speed of light. In fact, it was exactly

electrodynamics considerations that led Albert Einstein to the formulation of the special theory of relativity and to demonstrate that magnetic fields are just the manifestations of electric fields in a different coordinate system frame of reference (Griffiths 1999). Electromagnetism has a particularly elegant relativistic formulation which allows a natural extension of electromagnetic theory to the realm of relativistic phenomena. Quantum electrodynamics (QED) is the relativistic *quantum* field theory of electrodynamics. It was developed by a number of physicists, beginning in the late 1920s, and describes at a very fundamental level how light interacts with matter, i.e., all phenomena involving the interaction of electrically charged particles by means of exchange of virtual photons – the mediator or exchange particles providing the fundamental mechanism enabling the existence of the electromagnetic interaction force. QED was the first satisfactory quantum mechanical description of a physical field involving the processes of creation and annihilation of quantum particles. It has served as a successful model for the development of all subsequent quantum field theories. QED showed that there are both observable and unobservable photons and that the electromagnetic force between electrically charged particles is carried by the unobservable ones – the virtual photons (Fagg 1996). Although virtual photons cannot be directly observed, their existence is certified by the fact that without including them, QED calculations could not yield results which are in agreement with experiments.

Electrodynamics, Optics, and Religion

The relationship between electrodynamics, optics, and religion could be considered from several different perspectives. *The first one* is based on the fact that both Michael Faraday and James Clerk Maxwell – the key figures behind the development of the theory of electromagnetism – were authentically religious people, and, according to some, it was precisely their religious worldview that made it possible for them to create a dynamic theory of the electromagnetic field (Torrance 2002). *The second perspective* is based on the universality and on the pervasive nature of

the electromagnetic force. Fagg (1996) points out that any viable natural theology must understand and meaningfully interpret the electromagnetic force in its “awesome” universality: “The electromagnetic force provides a simplifying and unifying influence that has not yet been seriously considered by natural theologians, and it needs to be. . . . [T]he universality of the electromagnetic force must constitute one of the central ingredients and cohesive bases in natural theology. This hypothesis is based not only on the premise of the universality of the electromagnetic force in general but also on the nature of the photon of electromagnetic radiation, or light, the carrier of this force, in particular. The primality of light as a salient feature of the universe since primordial times, as an indispensable element in our daily lives, as a means of communication for all humankind, and as a manifestation of divine presence suggests a uniquely proximate connection between the physical and spiritual worlds” (Fagg 1996). It should be strongly emphasized that in the cases when this connection is applied in relation to the divine presence in the world, it refers to a relation between the created world and the eternal, uncreated God. According to Saint Augustine, in creation, there is nothing related to God the Trinity, except the fact that the Trinity has created it. The difference between created and uncreated is, therefore, so crucial that all of our human analogies about the two poles of this difference should be taken very cautiously, with a full appreciation of the deep and beautiful mysteries hidden in it (Florovsky 1976).

A third perspective enabling the discussion of the relationship between electrodynamics, optics, and religion could be based on the semantic richness of the field concept in the way it has been used as a metaphor signifying the immanent presence of God and the activity of the divine energies in space and time. According to Pannenberg (2006), “the potential of the field concept for the dialogue between science and theology has not been used until very recently . . .” The actualization of this potential, however, should focus on the similarity between the conceptual relationships (not between the concepts themselves) in the two different domains and on the ways of

their operation within their own proper context (Tanev 2009). Both quantum electrodynamics and theology refer to dynamic “nonclassical” realities, and it is only by taking into account of this dynamism that it is possible to escape potential ontological ambiguities and open additional epistemological opportunities. In both cases, the invisible nature of the dynamic realities leads to the need of interpretation. In both cases, the interpretation of the manifestations of these realities can lead to the danger of their forceful visualization since we always tend to interpret within the framework of our visual experience (Puhalo 2007). The tempting connection between interpretation and visual experience affects our language since the visual is easier to be expressed linguistically, and our linguistic and visual assumptions are not fully decoupled. The struggle against such forceful visualization of invisible, i.e., unseen, realities is common to both theology and modern physics.

Another perspective enabling the discussion of the relationship between electrodynamics, optics, and religion is based on the extensive use of *light* and *energy* as metaphors in theology. This is especially true in Eastern Christian (Orthodox) theology where the two concepts are present and fundamentally interrelated (Tanev 2009; Louth 2004). The theology of the Eastern Christian Church builds on the legacy of the Byzantine tradition where light, both artificial and natural, was extensively used and is still part of Orthodox worship today (Louth 2004). It is not a mere coincidence that one of the oldest hymns in the Orthodox Church is addressed to the joyful light of the glory of the Trinity which is symbolized by the lighting of the evening lamp at sunset: “as the sun sets, and with it the light of the world, the evening lamps symbolizes the eternal light of the Godhead (the light that knows no evening, as it is sometimes put)” (Louth 2004). In addition, the orientation and the architecture of the churches in the Middle and Late Byzantine periods were carefully calibrated to make use of the natural effects of the rising sunlight. “[T]he sills of the windows around the base of the dome were polished and fixed at such an angle that the horizontal rays of the rising sun were directed up on

the icon of Christ Pantocrator that looked down from the top of dome, with the result that in the darkness of the church the icon of Christ would seem to hover in the reflected light of the rising sun” (Louth 2004). This extraordinary care in using natural light has deeply theological reasons. It demonstrates the importance attached to the significance of light as a symbol of the coming of Christ, the Logos, and son of God, in the world in his Nativity and rising over the world in his Resurrection (Louth 2004). It is also profoundly biblical. In John 8:12 (NKJV), Jesus proclaims, “I am the light of the world. He who follows Me will not walk in darkness, but will have the light of life.” He is the One who gives the light of life. In the New Testament, God is light (1 John 1:5). The followers of Jesus are the light (Matt. 5:14), and the faithful shines as lights in the world (Phil. 2:15). In these and other references in the Gospel John (1:4–10; 3:19; 12:35, 36), God is the source of the uncreated, life giving light. The experience of this uncreated light refers to the encounter with the glory of the Godhead Himself and lies at the heart of Eastern Christian spirituality and of Byzantine hesychasm in particular. Hesychasm is a tradition of prayer based on the repetition of the Jesus prayer (Lord Jesus Christ, Son of God, have mercy on me, a sinner), under the direction of a spiritual father, which leads to a conscious experience of the presence of God, often in the form of a vision of light (Louth 2004). The theology of the experience of the uncreated divine light was a fundamental part of Byzantine theology. It was theologically refined on a number of synods in Constantinople in the middle of the fourteenth century to become inseparable part of Orthodox theology up to the present moment. The key theologian behind the doctrinal formulations of the synods in Constantinople is Saint Gregory Palamas (1296–1359), with his distinction between the divine essence and the energies, according to which God is unknowable in his essence but knowable in his energies (Louth 2004). The emphasis of this statement has two interrelated aspects. The first aspect is epistemological – in the divine energies, it is God Himself who is known and not merely something about God.

And according to the Gospel of John, life eternal consists in knowing God (John 17:3). The second aspect is soteriological since it points out that it is God alone who could save His people. God, however, is eternal, invisible, and personal and cannot be approached by means of our human ways of knowing. Our knowledge of Him, therefore, is always associated with His will – everything that we know about God is the result of divine revelation and the manifestation of His energies (or activities). Paramount among these divine energies is the uncreated light of the Godhead, the light in which Christ was transfigured before his disciples on Mount Tabor – the Taboric light (Louth 2004). According to Saint Maximus the Confessor (c. 580–662), the theological predecessor of Saint Gregory Palamas and of his theology of the divine energies, on Mount Tabor, it was actually Christ's disciples who were transfigured by the Spirit and made able to see His divine glory: “They beheld Him transfigured, unapproachable because of the light of his face, were amazed at the brightness of his clothes and in the honor shown Him by Moses and Elijah who were with Him on either side, they recognized his great awesomeness. And they passed over from flesh to spirit, before they had put aside this fleshly life, by the change in their powers of sense that the Spirit worked in them, lifting the veils of the passions from the intellectual activity that was in them. . . . They were taught hiddenly that the all-blessed radiance that shone resplendently from his face, as it overpowered the sight of the eyes, was a symbol of His divinity that transcends mind and sense and being and knowledge” (Louth 1996).

[Electroneurography; EMG](#)

Description

Electromyography (EMG) denotes a subdiscipline of clinical neurophysiology and

neurology (See ► [Neurophysiology](#)) recording muscle currents at rest and during activity by surface or by needle electrodes for research and for diagnostic purposes. Motor and sensory nerve conduction studies (electroneurography) are part of electromyography. EMG is of greatest diagnostic value in diseases of motor neurons, nerve, and muscle, while research applications are preferentially concerned with studies of normal and pathological movements and reflexes. The beginnings of clinical EMG after 1930 are associated with the names of D. Denny-Brown (1949) in North America and F. Buchthal (1985) in Europe (See ► [Neurology in Europe](#)), among others. A modern and frequently used summary of the current knowledge on clinical EMG is the comprehensive textbook by J. Kimura (2001).

Self-Identification

Science

The beginnings of EMG were merely scientific and were based on the technical development of modern electrophysiological amplifiers and oscilloscopes for displaying fast electrical muscle and nerve activity in the time domain of milliseconds. Another important step was the introduction of the concentric needle electrode by Adrian and Bronk (1929) and the subsequent observation of motor unit potentials by Denny-Brown (Mayer 2001). EMG has always self-identified as a biological and/or medical science following the rules of scientific work. In a period between 1930 and 1960, many EMG phenomena have been first described which separate normal muscles from those affected by muscle disease or by a peripheral nerve or motor neuron disorder. Findings such as fibrillation potentials, positive waves, fasciculation potentials, or myotonic discharges in resting muscles or myopathic and neurogenic changes in innervated muscles were described and scientifically classified (Caruso et al. 1999). The latter changes were statistically evaluated; normative values were developed and provided for quantitative EMG measurements (see Caruso et al. 1999).

Since then, EMG has remained an important research tool in studies of muscle and nerve in health and disease and could simultaneously be established as a routine diagnosis although it remained, to some extent, an art. In addition, EMG has increasingly been used for studies of physiological movements such as grasping, gait, or sports activities (See ► [Movement Disorders](#)). Consequently, the physiological findings were used to analyze pathological movements such as tremor, myoclonus (jerks), tics, and others in order to understand their pathophysiology (e.g., Dengler et al. 1986).

An important step forward was the introduction of digital techniques into neurophysiology starting in the 1970s. New amplifiers and monitors and also highly selective recording electrodes were developed in conjunction with methods such as single-fiber EMG (Stålberg & Trontelj 1997), allowing to investigate the function of the neuromuscular transmission in the microseconds domain and denervation and reinnervation in a quantitative way. Averaging techniques provided the possibility to record smallest nerve potentials of a few microvolts amplitude as required for sensory nerve conduction studies.

Modern EMG has in part become a routine tool in diagnosis and is still a science with a vast body of literature and several scientific journals dedicated to EMG research. Most modern and also developing countries have their national societies for clinical neurophysiology including EMG.

Characteristics

EMG is distinctive from other specialties of medicine in several aspects.

It is the only discipline to study electrical activity of nerve and muscle in order to conclude on their functional status. Thus, it has the potential to provide information on relevant functional changes of the neuromuscular system and to explain clinical phenomena such as muscle weakness, muscle fatigue, wasting, cramps, and others. This capacity of EMG is used for diagnostic purposes especially

in the field of neuromuscular disorders where EMG still plays a very important role.

Another difference to other helpful diagnostic approaches such as imaging by nuclear magnetic resonance tomography or muscle biopsy and morphological examination is that it is an office method providing immediate diagnostic information. It is to some extent an extension of a clinical neurological examination and can be performed repeatedly. It is economical and highly appropriate for monitoring the course of neuromuscular diseases.

Another important difference to other approaches of analyzing the neuromuscular function is that EMG works in the time domain of milliseconds and has a high time resolution. This is not only relevant in studying neuromuscular diseases but also in central motor or movement disorders (See ► [Movement Disorders](#)) when the exact analysis of movements or of reflexes is of great importance. It allows to detect the exact timing of the interaction of several muscles which is helpful in studying gait and its disorders, the various tremor forms, myoclonic movements, tics, spasticity, and several others.

Relevance to Science and Religion

EMG is clearly a biological science and plays its most important role in neurological medicine. It goes, however, beyond these borders as muscle activity and movement is part of human life in general and is the only possibility of man to get in touch with its environment and with other living beings including speech production. EMG is also used in psychological studies aiming at man-to-man interaction and, in particular, at interindividual communication. This psychophysiological potential of EMG makes it an interesting tool for interdisciplinary activities between neurosciences and humanities (See ► [Neuropsychology](#)).

Sources of Authority

The sources of authority of EMG are formed by neurophysiologists and clinical neurologists

who theoretically and practically developed EMG at the end of the second decade of the last century and made it an attractive and respected science. The approaches to EMG in experimental and clinical neurophysiology have been scientific from the very beginning. A large body of data was collected, analyzed, and published in well-renowned journals. In the following, normative data have been developed for diagnostic purposes which are still valid despite all technical new developments in this field. This material has been published in numerous books on EMG in the Anglo-American literature as well as in German language and is revisited from time to time. In nearly all countries with a developed health-care system, we find scientific societies which are in part or exclusively concerned with EMG. Mostly, these societies have the attribute “clinical neurophysiology” in their denotations, and sometimes, the term EMG appears. These societies take care for ascertaining the quality of EMG and also for education of young scientists and physicians and have contacts with health-care system authorities and industrial companies with regard to commercial aspects of EMG. An international society called “International Federation of Clinical Neurophysiology” (IFCN; <http://www.ifcn.info/>) forms the umbrella for the national societies and organizes communication between them, e.g., via regular international congresses with assemblies of the member society delegates. The IFCN also publishes guidelines for practicing EMG and defines the appropriate EMG terminology (Caruso et al. 1999). It supports the development of high-quality EMG in economically disadvantaged countries.

Ethical Principles

EMG follows the ethical principles expressed in the famous “Oath of Hippocrates.” It has also adopted the rules of the “Declaration of Helsinki.” For scientific use of EMG, it is obligatory to apply to the local ethical committees and ask for permission.

Key Values

One key value of EMG is to make a contribution to the diagnosis of diseases of the neuromuscular or the central motor system. Another is to support research focusing on the normal and the pathological function of the motor system (Kimura 2001; Stålberg & Falck 1997).

Conceptualization

Nature/World

EMG conceptualizes nature as the basic mechanisms of life and the environmental forces with special regard to those influencing the motor system. World has no special meaning in EMG except for the classification of countries according to their economical status and their capacities to develop EMG.

Human Being

EMG has no special definition of human beings. It understands itself as a discipline which serves human beings in health problems.

Life and Death

EMG associates life with muscle activity which is indeed the way how living beings make contact with their environment. Even basic signs of life such as heartbeat and breathing represent muscle activity. The origin of life is closely associated with muscle activity or contractions on a microscopical level as seen in bacteria, etc. Death is the absence of such activity.

Reality

Reality in EMG is recordable electrical muscle activity.

Knowledge

Knowledge in EMG is fairly identical with expertise in the art of EMG.

Truth

Truth is a term not used in EMG. The guideline for EMG is evidence-based knowledge.

Perception

Perception in the field of EMG mainly refers to the awareness of muscle contractions or movements.

Time

Time is an important parameter of EMG as all electrical events have a time dimension. EMG measures phenomena in the domain of milliseconds and even microseconds.

Consciousness

Consciousness is a construct of the brain. EMG does not contribute to the understanding of consciousness although movements may be a sign of consciousness.

Rationality/Reason

Rationality is important in science. EMG can, however, not contribute to its definition.

Mystery

There are mysteries in medicine and also in EMG, i.e., objectively recordable phenomena which can currently not be explained.

Relevant Themes

EMG has always been a biological science and a subdiscipline of clinical neurophysiology. It is part of the world of natural sciences and has little relationship with faith or spirituality which is prevailing in religion.

[Nerve conduction study](#)

Description

Electroneurography refers to the technique used to test and quantify the nerve conduction and impulse propagation along motor and sensory nerves. A synonym is nerve conduction study. In principle, a peripheral nerve is stimulated by a short electrical pulse usually applied transcutaneously. The responses are recorded using electrodes applied over the muscle innervated by the nerve (motor nerve conduction), from the skin (sensory nerve conduction) or from another part of the nerve (mixed nerve conduction). The time the impulse takes to travel from the stimulation to the muscle is called distal motor latency and is measured in milliseconds. The amplitude is a measure of the number of nerve or muscle fibers activated.

The stimulation has to be strong enough to activate all nerve or muscle fibers. By stimulating the nerve at two different sites along the nerve, the motor conduction velocity can be calculated by dividing the distance by the latency [m/s]. In sensory fibers, recordings are done with electrodes applied to the skin. Sometimes, needles are used for recording the signals. The time between the stimulus and the response is measured and the sensory conduction velocity is calculated. The amplitude of the sensory nerve action potential represents the number of sensory fibers activated. The impulse travels along the nerve in both directions. Some of the action potentials travel to the spinal cord and back resulting in late responses called F-waves. This provides information on the conduction of the proximal nerve segments. Electroneurography is used to evaluate the nerve conduction in neuromuscular disorders. Slowing of the conduction velocity is due to acquired or inborn problems of the myelin in patients with demyelinating polyneuropathies or repeated nerve compressions. The lack of conduction across a nerve segment is called conduction block, which can be complete or partial. It is mostly a sign of an acute peripheral nerve compression. In axonal neuropathies, the conduction velocity remains normal or is only slightly reduced, but the amplitudes of the motor compound action potentials are low. Low amplitudes are also found in patients suffering from loss of alpha-motoneurons and in patients with loss of muscle fibers (myopathy). To make a further differentiation of neuromuscular disorders, electroneurography is frequently combined with the electromyography.

Axon	Inner part of a peripheral nerve
Myelin	Outer part of the nerve
Electromyography	Investigation of the muscle using needle electrodes inserted into the muscle
Polyneuropathy	Disorder that damages more than one nerve at the same time, mostly the longest nerves (to the feet) are damaged first

Description

The development of electronics has a direct impact in computers; the first computing devices were mechanical with limitations in size and processing speed. With the invention of the transistor in 1947 and the integrated circuit in 1958 (Lee 2007), a new approach for computing devices was possible using the binary system for instructions and data in digital computers. Boolean logic is implemented in electronic circuits by using transistors on-off states as true-false (one-zero) logic.

Since the invention of the transistor (electronic switch in digital electronics), research has been focused on the integration of these

building blocks into small chips; integration has reduced the size and cost of computers and other electronic devices (Branscomb 1982). The actual trend in microelectronics is known as Moore's law: the number of transistors in an integrated circuit doubles every 18 months. Some integrated circuits have become classic designs and are still in use today in spite of being fabricated long time ago, for example, the processor Z80 (Santo 2009). Moore's law cannot continue indefinitely, new physical properties emerge when circuits are reduced to the scale of nanometers; fabrication costs and power dissipation are important obstacles to overcome when reducing the size of integrated transistors.

Current research is looking for new implementations of transistors by using materials and devices at the nanometer scale, transistors with carbon nanotubes or graphene. Also new architectures for information processing and memory are being explored such as memristor crossbars (Strukov et al. 2008).

Self-identification

Science

Electronics, computer devices, and integrated circuits are based on first principles from chemistry, solid-state physics, and quantum mechanics. These devices are the result of mathematical theories, models, computer simulations, and experiments. Digital circuits rest on scientific discoveries and follow the laws of nature.

Characteristics

Electronic circuits are modeled, developed, and tested before the actual implementation as integrated circuits in solid state; these circuits follow mathematical models and natural laws. The main characteristic of electronic circuits for computers is a solid background in experiments and theory; years of research and development are needed to produce commercial devices.

Relevance to Science and Religion

There are no links between electronic circuits for computers and religion. This discipline is not interested in the area of science and religion.

Sources of Authority

The discipline rests on physical laws, mathematical models, experiments, and numerical simulations. There are well-known contributors to the field but these people are related to discoveries or ideas rather than authority; all principles can be proved or tested in a laboratory without support from authority. Circuits must follow mathematical models and natural laws independent of authorities.

Ethical Principles

All ethical principles of mankind are valid.

Key Values

Respect for human life, improvement of human quality of life, sustainable exploitation of natural resources.

Conceptualization

Nature/World

Source of inspiration and natural resources.

Human Being

Center of activity, goal, motivation to improve devices, happiness.

Life and Death

Valuable.

Reality

Where devices are tested, continuous work to understand it.

Knowledge

Fundamental and in permanent search.

Truth

Electronic devices must perform without divine intervention or authorities.

Perception

Source for devices operation.

Time

Main variable, computing speed is a goal.

Consciousness

It does not apply.

Rationality/Reason

Digital circuits are designed using Boolean logic.

Mystery

There is no room for mystery; circuits must work in a predictable way.

Embodied Theology

Johanne Stubbe Teglbjærg

Related Terms

[Somatology](#)

Description

Embodied theology is a new kind of theology, which has, in recent years, developed throughout the world. It is distinguished by a particular methodological awareness, rather than by a specific theological content. This theology is embodied in the sense of a methodological concern with its own embodiment as a condition for its thought. It is theology through the body and not theology

about the body, as for example a body-theology or somatology would be even though embodied theology always implies a certain notion of the body. Instead, it is defined by its methodological awareness that theological reflection is embodied too. This means that it is not only methodologically concerned with the embodiment of theological reflection in general, but with the embodiment of its very own reflection. It is, however, controversial how this particular methodological awareness should be theologically expressed, since an embodied perspective challenges the very concepts of particularity and method from within. It cannot be defined as a strict method, but must be viewed as an embodied approach, which can sometimes be described as a mood that defines this kind of theological thought. Some emphasize the diversity of the approach rather than its unity.

Embodied theology is motivated by what it takes to be an increasing interdisciplinary awareness of human embodiment and of reflection as embodied in the radical sense of the word. However, it is contested whether this theology is driven primarily by strict, internal, theological concerns for embodiment, as indirectly expressed for example in the doctrines of incarnation and resurrection of the body, or whether it springs from a more external and contextual development, as in the phenomenological discovery of the body or corporeal turn in philosophy. What is clear, however, is that embodied theology has also developed as a reaction against a diverse field of dualistic tendencies in religious thought, for example tendencies toward epistemological dualism (where the subject is considered separate from the object); anthropological dualism (where the soul or mind is considered separate from the body); or cosmological dualism (where human beings are considered separate from the rest of the cosmos). In embodied theology, the effect of these dualisms is generally viewed as distortive, since they are believed to have destructive implications in terms of anthropocentrism, individualism, subjectivism, and intellectualism. Correspondingly, embodied theology typically stresses the importance of what is regarded as the experienced and constitutive relation between

subject and object, mind and body, and human beings and the cosmos. In spite of rejecting dualism, embodied theology does not by definition adhere to monism since it recognizes a theological, philosophical or experiential fact of dualisms.

It is possible to distinguish different movements in embodied theology currently in development. These are embodied theology in traditional theologies, in contextual theologies, in postmodern theologies, in phenomenological theologies, and within the dialogue between theology and science. However, even though these movements are framed within the context of traditional theological debates, it should be noted that the very notion of embodiment is widely recognized as challenging these traditional theological distinctions. A more elaborate description of embodied theology, thus, depends on their various methodological and conceptual assumptions about the body and its context.

In *traditional* (conservative as well as liberal) theologies, embodied theologies are neither common nor well defined. Frequently, embodied theology is viewed as proceeding from the embodied tradition of the church. However, what this means specifically is subject to a great variety of interpretations. This kind of embodied theology presupposes an understanding of the body as a tradition, which is distinct from other traditions, and which, therefore, displays a certain concept of privacy. Consequently, this assumes an understanding of the body as a given, non-constructed, and private context of meaning.

In *contextual* theologies such as Liberation, Black, or Feminist theologies, embodied theology calls for an alternative to traditional theologies, which are seen as dualistic and oppressive. It is claimed that dualism leads to alienated and violated human beings. A notion of the body as a cultural construct and an expression of the most fundamental level of power relations among humans are implied in these theologies. Yet, in embodied contextual theology, the body is viewed as a source of revelation that can be liberated and speak for itself. Because the body is viewed as a political field, embodied contextual theology becomes political theology. However, as

political theology, it does not necessarily move within preestablished political categories. Rather, it can challenge such categories from the perspective of embodied experience. Typically though, it presupposes a fundamental relation between reason and feeling and expresses human becoming through interpersonal relationships as well as through sexual desire. In contextual theologies, embodied theology is therefore not simply to be equated with a theology of context and culture, but more often occurs as counterculture.

Within *postmodern* theologies (radical or moderate), both the construction and non-construction of the body are questioned. It is argued that tradition and culture not only shape the body, but that the body is naturally or phenomenologically given and thus shapes this feature too. Embodied, radical, postmodern theology, which tends to weigh the notion of the body as a potentially liberating construction, implies a theological call for developing a positive distance to the given and consequently more discarnate and disinterested being. However, moderate postmodern theology calls for a third path between total disengagement and absolute engagement. In this moderate context, embodied theology is explicitly aware that the body is not only what we think, but also what we think with. The body is not merely constructed (by tradition or by us) as an object from which we can distance ourselves by creating a new notion, but must be seen as a constitutive feature of subjectivity.

This kind of embodied, moderate, postmodern theology is related to embodied theology as developed from a phenomenological perspective, which is currently affecting the dialogue between *theology* and *science*. The theology-science issue has typically presupposed a view of the body as a kind of object or aspect of objectivity, whether such an object is explained in realist, physicalist, materialist, or naturalist categories – or described within the framework of a non-reductive, dual-aspect monism. As an aspect of objectivity, the body points to a scientific context for theology which gives rise to certain scientific demands, such as greater objective validity and empirical progression. However, in continental

phenomenology the body is described as a third way of being in the world, between the modes of pure subjectivity and objectivity or a way of being, which mediates between or even synthesizes the inner and the outer. According to phenomenology, embodied meaning is enacted, embedded, and extended. This implies that the body cannot be defined in purely private or collective categories, but rather must be addressed through the experience of intersubjectivity. Consequently, embodied theology of this kind explicitly thematizes the notions and relations of its own subjectivity, alterity, and ambiguity. This brings embodied, phenomenological theology into a close relationship with other sciences, but in a way that is quite different from the traditional – whether naturalistic or hermeneutical – manner of relating theology and science.

In describing embodied theology, other distinctions could be used than those applied above. For example, could one distinguish between the traditions of subjective, objective, and phenomenological thought, or between a “body-positive” and a “body-negative” theology. However, such distinctions might be problematic because it might be argued that they are undermined by an awareness of the body as an ambiguous mediator between subjectivity and objectivity.

Related Terms

[Emergent phenomena](#); [Fulguration](#)

Our deepest interests in “what there is” and “what it is” traditionally give rise to two quite different approaches: a *diachronic* one on how things have developed and a *synchronic* one on how the makeup of things relates to their particular behaviors, dispositions, and properties. Correspondingly, nearly all religions offer stories about how the universe, matter, living beings, and particularly, human beings came into existence and how they relate to each other. But religious accounts of the origin of life, mind, and spirit do not provide the very context in which theories of emergence enter stage, although many theories of emergence address the same issues. Theories of emergence come into play in the context of

scientific approaches to understanding ourselves and the nature around us, and they, too, comprise diachronic and synchronic versions.

The basic idea of emergence is that as systems become increasingly complex during evolution, some of them may exhibit *novel* properties that are neither *predictable* nor *explainable* on the basis of the laws governing the behavior of the systems' parts. Particularly, complex wholes can come to have properties that are *not reducible* to the arrangement and the properties of their components. Accordingly, in metaphysics, epistemology, and philosophy of science, the meaning of "emergence," being "emergent," and to "emerge" is associated with features such as being "novel," "unpredictable," and "irreducible." Hence, we should be aware of the crucial difference between the technical usage of these terms and their use in ordinary language, where to "emerge" roughly means to "appear," to "rise above a surrounding medium," or to "come into view (or existence)." The only connection between ordinary and philosophical usages of these terms is that entities that emerge in evolution (or otherwise), in the ordinary sense of the word, may be good candidates for being emergent in the technical sense.

After a brief sketch of the historical development of emergentism (a comprehensive overview is offered by Stephan 2007), I will focus on a systematic account of the varieties of the concepts and theories of emergence. Eventually, I comment curtly on the relationship between theories of emergence and religious issues.

The history of emergentism comprises several ups and downs (cf. Brian McLaughlin's "The rise and fall of British emergentism" in Beckermann et al. 1992). It has seen its early heydays at the beginning of the twentieth century when in rapid sequence, the major works of British and American emergentists appeared: in 1920 Samuel Alexander's *Space, Time, and Deity*; in 1922 Roy Wood Sellar's *Evolutionary Naturalism*; in 1923 Conwy Lloyd Morgan's *Emergent Evolution*; and in 1925 Charles Dunbar Broad's *The Mind and its Place in Nature*. Most of these philosophers' theories of emergence are reactions to the philosophical debate on the nature of life

and mind. While vitalists like Hans Driesch and Henri Bergson claimed, for the explanation of vital and mental processes, the existence of supernatural entities such as an *entelechy*, a *psychoïd*, or an *élan vital*, biological mechanists were convinced that they could reduce without residue all phenomena of life and mind to physical and chemical processes. Both vitalism and mechanism, however, were thought to have implausible consequences: substance-dualistic approaches, on the one hand, violate the principle of the causal closure (i.e., If x is a physical event and y is a cause or effect of x, then y, too, must be a physical event), of the physical domain and are hard to square with evolutionary cosmologies; mechanism, on the other, does not seem to capture the genuine organic and mental processes adequately, it particularly failed to explain phenomenal experiences. The emergentists steered a middle course. They denied both substance-dualistic and reductionist theories: they were *nonreductive naturalists*.

The development of early British emergentism itself has its roots in the work of John Stuart Mill, Alexander Bain, and George Henry Lewes. Although we can find some precursors of emergentist thinking already in ancient philosophy, particularly in the work of Galen, and in continental philosophy, the proper development of theories of emergence begins in the mid-nineteenth century in Britain. In his book *Problems of Life and Mind* Lewes (1875) introduced the term "emergent" into philosophy, to distinguish *emergent* from *resultant* effects. Herewith, he picked up on a distinction Mill had drawn between *homogeneous* and *heterogeneous* effects in his magnum opus *A System of Logic. Ratiocinative and Inductive* (1843). Joint effects of causes are called heterogeneous effects (or "emergent") if they are not the *sum* of their separate effects; otherwise they are called homogeneous. His thought was that homogeneous cases obeyed principles of vector composition and were additive; by contrast, in heterogeneous cases, there was a failure of vector composition or additivity. The products of chemical interactions, for example, were evidently qualitatively different from the substrates that grounded the

reaction. Mill's further distinction between *ultimate* and *derivative* laws was also of great importance for the development of emergentist ideas. In particular, Broad took up Mill's distinctions and his subsequent considerations about the limits to the explanation of psychophysical laws when he developed his "classical" notion of strong synchronic emergence (see below; for further details on Mill's impact on British emergentism, see Stephan 2007, Chap. 6).

In the following decades, theories of emergence were discussed vividly on conferences and in special issues. However, the criticism by the logical positivists Carl Gustav Hempel, Paul Oppenheim, and Ernest Nagel seemed to put an early end to emergentism, for their analyses in *Studies in the Logic of Explanation* (Hempel & Oppenheim 1948) and *The Structure of Science* (Nagel 1961), respectively, led to a squarely uninteresting and unpromising concept of emergence being relativistic in several ways and purely epistemic. The upshot of their thoughts is that there is no reason to treat emergence as an ontological trait of any property, rather it should be seen as indicative of the scope of our knowledge at a given time; what may be called emergent with respect to theories currently available may lose this status in the near future when better scientific theories have been developed.

With the decline of positivism, interest in metaphysical questions returned. It is the still unsettled question about the nature of mental states that has helped nonreductive approaches and particularly, emergentism to return to the philosophy of mind (cf. the contributions of Beckermann and Kim in Beckermann et al. 1992). During the last two decades, however, the idea of emergence not only has seen a strong revival in philosophy of mind but in many different fields and disciplines such as physics, biology, social sciences, religious studies, artificial life, robotics, connectionism, dynamical systems theory, theories of self-organization, and theories of creativity (important anthologies are, among others, Beckermann et al. 1992; Bedau and Humphreys 2007; Clayton and Davies 2006; Corradini and O'Connor 2010). In these fields,

the notion of emergence, however, is far from being used in a uniform way.

Hence, it is highly controversial what the criteria are by which "genuine" emergent phenomena should be distinguished from nonemergent phenomena. Some of these criteria are very strong, so that few, if any, properties count as emergent. Other criteria are inflationary in that they count many, if not all, system properties as emergent. One of the consequences of this controversy is a great confusion about what is really meant, when some property is called "emergent." In the next part of this chapter, I therefore offer a structure of the varieties we currently encounter within emergentist thinking.

The various kinds of emergence that have been suggested thus far can be structured according to three different dimensions: first, it is an issue whether the notion of emergence refers to an *epistemological* or a *metaphysical* (i.e., an ontological) relationship; second, whether it refers to a *synchronic* or a *diachronic* relationship; and third, whether it is introduced as a *weak* or rather a *strong* notion.

Most of the more ambitious theories of emergence and in fact, all *classical* approaches of the British emergentists are based on a common basal notion of emergence from which they can be developed by adding further and more demanding features (cf. Stephan 2007, Chap. 4). This *weak*, *synchronic* and *metaphysical* notion of emergence specifies the *minimal* criteria for emergent properties. It comprises three features: the thesis of *physical monism*, the thesis of *systemic properties*, and the thesis of *synchronic determination*.

The thesis of *physical monism* is about the makeup of systems that have emergent properties or structures. It claims that the bearers of emergent features consist of physical entities only and rejects all substance-dualistic positions such as vitalism or Cartesian dualism, which, for example, attribute properties such as being alive or having cognitive states to supernatural bearers (e.g., an *entelechy* or a *res cogitans*, respectively).

According to the second thesis, only *systemic* properties are candidates for emergent properties.

These are system properties that are *different in kind* from those had by the system's proper parts (i.e., parts on a lower level of organization). It is uncontroversial that many systems exhibit systemic properties. Thus, it is among the properties of a horse to neigh and whinny, but no proper part of it (head, heart, nor any cell assembly) can whinny; it is among the properties of a connectionist network to generalize and to recognize patterns, but no single part of it (e.g., a unit or connection weight) has this property.

The thesis of *synchronic determination* specifies the relationship that holds between the systemic properties of a system and its microstructure (i.e., the specific arrangement of the system's parts together with their properties). Systemic properties and dispositions depend nomologically on the microstructure of their bearers. There can be no difference in a system's systemic properties without some difference in the properties or arrangement of its parts. (Often, the latter claim is also referred to as a thesis of mereological supervenience.)

Anyone who denies the thesis of *synchronic determination* either has to admit systemic properties that are not dependent on the microstructures of their bearers, or she has to suppose – contra the thesis of physical monism – that some additional factors, for example, nonnatural entities, are responsible for differing systemic properties and dispositions of otherwise physically identical systems. One may have to admit, for example, that there may exist objects that have the same parts in the same arrangement as diamonds but lack the diamond's hardness. This seems implausible. Equally implausible is the idea that there may exist two physically identical organisms, one viable and the other not. In the case of mental phenomena, opinions may be more divided, but one thing seems to be clear, anyone who believes, for example, that two physically identical human beings could be such that one suffers, say, from aphasia while the other does not, also declines the first thesis of weak emergentism, namely, physical monism.

Weak, synchronic and metaphysical emergence is equivalent to what Robert van Gulick has called *modest kind emergence*

(cf. van Gulick 2001, p. 17). This type of emergence is also compatible with contemporary reductionist approaches. Particularly for this reason, philosopher of science Mario Bunge is emphatic about it, but also several cognitive scientists, for example, Francisco Varela, David Rumelhart, and James McClelland, to mention just a few, adopt this position.

Van Gulick considers an even weaker type of synchronic metaphysical emergence, namely, *specific value emergence*: this obtains whenever a whole and its parts have features of the same kind but have different subtypes or values of that kind (the mass of a whole, e.g., is different in value from the mass of any of its proper parts). Nobody, however, has ever thought to characterize specific values as *emergent* properties. Quite contrary, from the very beginning of British emergentism, features of wholes, which differ only in value but not in kind from features of their parts, have served as a contrast class for emergent properties. This is already present in Lewes's distinction between *resultant* and *emergent* effects, for which nonadditivity is the decisive feature. Hence, there is no reason to treat specific values as emergent properties at all, since usually their bearers share them in kind with their components.

On the other side of the spectrum, van Gulick presents a much stronger type of synchronic metaphysical emergence, namely, *radical kind emergence* (van Gulick 2001, p. 17). In this case, a whole is thought to have features that are not necessitated by the system's microstructure, i.e., the properties of its parts, their mode of combination, and the law-like regularities governing the features of the parts. William Hasker's proposal of what he has coined "emergent dualism" together with the postulation of the mind as an emergent individual (a *soul field*) is a case in point of radical kind emergence, since he explicitly denies that all mental processes are supervenient on brain processes (Hasker 1999, pp. 194–195). Radical kind emergence, thus, rejects one of the core elements of traditional theories of emergence, which also is a center piece of Broad's classical definition (see below) and the third feature of weak synchronic

emergence as introduced above: *synchronic determination*. Jaegwon Kim, one of the most distinguished participants in the current debate on emergence, therefore doubts with good reasons whether radical emergence gives us a form of emergence at all (cf. Kim in Clayton and Davies 2006, p. 192).

Among the more ambitious *epistemological* notions of emergence both a *synchronic* and a *diachronic* version deserve closer attention. While both share the features of weak emergence, they differ with respect to the features of *irreducibility* (synchronic emergentism) and *unpredictability* (diachronic emergentism).

The idea of *strong synchronic epistemic* emergence has its origin in Broad's theory of emergence. Broad's definition of emergence which he developed in sharp contrast to the mechanistic worldview might be the most quoted passage in emergentism; it reads: "Put in abstract terms the emergent theory asserts that there are certain wholes, composed (say) of constituents *A*, *B*, and *C* in a relation *R* to each other; that all wholes composed of constituents of the same kind as *A*, *B*, and *C* in relations of the same kind as *R* have certain characteristic properties; that *A*, *B*, and *C* are capable of occurring in other kinds of complex where the relation is not the same kind as *R*; and that the characteristic properties of the whole *R(A,B,C)* cannot, even in theory, be *deduced* from the most complete knowledge of the properties of *A*, *B*, and *C* in isolation or in other wholes which are not of the form *R(A,B,C)*. The mechanistic theory rejects the last clause of this assertion" (Broad 1925, p. 61). The second clause of this definition is, by the way, Broad's formulation of the principle of synchronic determination that radical kind emergence would deny. As its core feature, however, this definition comprises the *irreducibility* (or nondeducibility) of certain systemic properties, i.e., the principled failure of reductive explanations of these properties.

Closer scrutiny, however, reveals that three different sorts of irreducibility claims are hidden in Broad's definition. They come to the fore by studying the conditions reductive explanations must meet to be successful. Generally, we ask for reductive explanations when we want to

understand *why* a certain entity instantiates a certain property, in fact a property that is only attributed to the system as a whole. So, the aim of each reductive explanation is to explain a system's dispositions and properties solely by reference to its components, their properties, arrangement, and interactions. To be successful, several conditions must be met: first, a property to be reduced must be functionally specifiable; second, it must be shown that the specified functional role is filled by the behavior of the system's parts; and third, the behavior of the system's parts must follow from the behavior they show in simpler systems than the system in question. If all conditions are met, the behavior of the system's parts in other contexts reveals what systemic properties the actual system has.

Since the three conditions are independent of each other, we have to distinguish three different types of strong synchronic emergence, which in turn have three different implications. If a systemic property is irreducible due to the fact that the components' behavior, given their current arrangement, is not reducible to the behaviors they show in simpler systems, then the system itself (or its specific structure) seems to exert some "downward causal influence" on its parts. However, such downward causation would not violate the principle of the causal closure of the physical domain. We would just have to accept additional types of causal influences within the physical domain besides the known types of mutual interactions.

On the other hand, if it is impossible to show that the behaviors of the system's parts fill the causal role adequately attributed to the functionally specified systemic property, this systemic property itself seems to have causal powers different from those of the system's microstructure. If in addition, the systemic property were a nonphysical (mental) property with a causal influence on the physical world, we would have to admit a violation of the principle of the causal closure of the physical realm.

In contrast, the occurrence of properties that are not functionally specifiable at all is neutral concerning downward causation. It neither implies nor excludes downward causation.

Systems with properties that admit of no functional analysis need not be constituted by components whose own behavior is irreducible. Nor is it implied that the system's structure has a downward causal influence on the system's parts. It may just be that some of the system's properties are *nonstructural* properties, i.e., basic properties whose instantiation does not consist in the instantiation of distinct properties by the system or its parts as O'Connor and Wong have claimed. O'Connor and Wong, however, introduce nonstructurality as a metaphysical (and not as an epistemological) feature of emergent properties in a strong sense. In addition, they think that novel causal powers might be conferred on the system by its own emergent features (cf. O'Connor and Wong 2005, pp. 665–667).

Among the properties, dispositions, and behaviors to be reductively explained, mental properties take an exceptional position: they are considered as remarkably intractable. Some authors even doubt that we ever might succeed in reductively explaining certain mental properties, such as phenomenal experience, intentionality, or free agency. Even if we would know everything about the neural correlates of consciousness, even if we could say how each single neuron and how each single synapse behave, we might not be able to reductively explain all mental properties correlated with these neural processes. In fact, such a failure would not be based on a lack of insight on the side of the neurosciences; rather it would come along with the conceptual impossibility to adequately reconstruct phenomenal qualities via their functional role. And this principled failure might be due to the fact that phenomenal properties are nonstructural properties.

Let us now turn to *diachronic* theories of emergence. These theories are all based on a thesis about the occurrence of *novelties* in evolution. According to this thesis, in the course of evolution, exemplifications of genuine novelties occur again and again. Existing entities combine to new configurations and structures that constitute new entities with new properties and behaviors. However, the idea of a sequence of novelties does not by itself turn a weak theory of

emergence into a strong one, since reductive physicalism remains compatible with it. Only the addition of the thesis of *unpredictability*, in principle, will lead to stronger forms of *diachronic* emergentism.

The structure of an arising new system can be unpredictable, in principle, for two reasons: its arrangement may be a result of indeterministic processes or it may be the result of deterministic but chaotic processes. Within emergentism, only the second option is discussed. It is captured by the thesis of *structure unpredictability*, which claims that the rise of a novel structure is unpredictable, in principle, if its formation is governed by laws of deterministic chaos. Likewise, any property that is instantiated by such a novel structure is unpredictable, in principle.

Emergence as *structure unpredictability* has a great deal in common with an approach Andy Clark has called emergence as *uncompressible unfolding*. This expression refers to those patterns or macrostates of a system that can only be derived by *complete* simulations of all interactions at the component's level and the external influences on the system (cf. Bedau in Corradini and O'Connor 2010, p. 52). Such complete simulations of the underlying microdynamics would also be necessary for long-term predictions of structure formations governed by deterministic chaos. Since these simulations are not available – information compressing short cuts are not adequate for longer intervals – structure unpredictability as introduced above is unpredictability, in principle. Mark Bedau who once introduced the simulation-based notion of emergence in the context of game-of-life environments unfortunately dubbed it *weak* emergence, too, to distinguish it from the *strong* synchronic type, which comes with irreducibility. The game-of-life was invented by the mathematician Conway and is a two dimensional cellular automaton, on which, based on a few mathematical rules, one can define complex structures and mechanisms, which exhibit interesting similarities to biological systems.

Recently, Paul Humphreys has argued that the criteria for synchronic emergence are not sufficient for a state or property instance to count as

emergent because the historical development of a system's dynamic is often crucial for them being emergent. This criticism overlooks, however, that both synchronic and diachronic as well as both epistemological and metaphysical notions of emergence have fruitful applications. Important is to keep them apart.

Typically, in scientific and philosophical debates about emergence, religious issues do not play a prominent role. In the history of emergentism, only Conwy Lloyd Morgan and Samuel Alexander, who see themselves in the tradition of Spinoza and who had a strong mutual impact on each other (cf. Stephan 2007, Chap. 1), comment in their works on both divine qualities and the conception and role of God in evolution (Alexander in the fourth book of *Space, Time, and Deity*; and Lloyd Morgan in the first lecture of *Emergent Evolution*, where he discusses Alexander's ideas). Their general goal is to give a philosophical interpretation of nature as a whole by conceiving of emergent evolution as a *natural* development through and through, which is barred from any "alien influx" or a "designing mind" at particular occasions. Alexander, however, holds a rather unique position concerning the ultimate basis and the putative result of nature's development. In his highly speculative metaphysical inquiry, he postulates *space-time* as the basal, ubiquitous, and all-pervasive entity. In addition, he assumes an activity (a metaphysical principle, he termed *nisus*) that leads the universe from certain constellations of space-time to matter and in further succession – via physical structures and chemical syntheses – to life, mind, and consciousness. Eventually or so Alexander thought, mind may be productive of a new emergent quality he called *Deity* – a quality he attributes to the highest natural systems, yet finite beings. In this picture, he equates God (as an actual existent) with the infinite universe with its *nisus* toward deity. Accordingly, Lloyd Morgan transcends what scientifically can be argued for, when he states that *emergent evolution* itself may be conceived as the expression of an omnipresent Divine Activity, which is manifested in every one of the multitudinous entities that emerge in evolution. Understandably, these issues

did not bother many philosophers and scientists when debating the prospects of emergent properties in physics, chemistry, biology, and cognitive science. Only recently, Philip Clayton took up theological questions when discussing the relationship of emergence and transcendence (Clayton 2004). There he weighs the costs of linking emergence with theism to expand the explanatory repertoire for treating our "big questions" about agency, responsibility, and freedom. These questions can, however, also be touched within a pure naturalistic framework of emergence (cf. Corradini and O'Connor 2010, part II).

Description

“Emotions” were traditionally viewed and conceptualized as a heterogeneous group of spontaneously arising subjective states associated with a variety of thoughts, behaviors, and bodily responses. The word “emotion” is derived from the Latin word *exmovere* meaning “to move,” “to stir,” “to set in motion” which was referred to as mental movement or agitation. Thus, traditional accounts of emotions represented in various branches of the humanities, such as literature, philosophy, and religion, have been grounded in subjective experience (Damasio 2003; LeDoux 1996). Emotions have been recognized as powerful factors influencing thinking and behavior. As such, they were often regarded to play a crucial role in all the dimensions of human experience, including religious experience and practice (Azari and Birnbacher 2004). In contrast to thinking or reasoning, emotions were often viewed as irrational.

Although historically emotions have been a subject of analysis by many thinkers and philosophers, such as Aristotle, René Descartes, Baruch Spinoza, David Hume, to name the few, the science of emotions started in the second half of the nineteenth century with the works of Charles Darwin, William James, and others. Darwin’s observations described in *The Expression of the Emotions in Man and Animals* pointed at the universal and evolutionary character of emotional responses (Darwin 1872). Evolutionary perspective enabled studying emotions through their expressions independently of subjective (conscious) reports (Darwin 1872; Ekman 2003). It also paved the way to investigating human emotions through animal research. For centuries, emotions were perceived to be connected to various bodily responses, such as changes in heart rate and respiration, sweating, shaking, dilation or constriction of pupils, and many others. It was commonly accepted that emotions trigger and change bodily states. This view was first questioned in the 1880s by William James and Carl G. Lange, who independent of each other proposed that emotions arise from

bodily states (James 1884). At the time when the James-Lange “peripheral” theory of emotions was formulated, there was little empirical evidence supporting their claims. On the contrary, clinical and laboratory findings, such as observations of patients with severed spinal cord or experiments on animals with disrupted major sensory pathways, suggested presence of emotional responses despite the apparent disconnection between the brain and periphery. One of the early critics of the James-Lange theory, Walter B. Cannon, argued that bodily responses would be too slow to generate emotions and would lack the specificity necessary to distinguish between one emotional state and another (LeDoux 1996). Cannon proposed that the hypothalamus, an evolutionary old brain structure, plays a crucial role in emotion. Whereas Cannon’s contemporary, Charles Dana, emphasized the role of brain cortex in generating emotional responses (LeDoux 1996). Thus, with the works of Cannon and others, the focus in emotion research was shifted from studying bodily responses to investigating the brain. The first brain-based model of emotion circuitry was formulated by James P. Papez in 1937. Papez proposed that a network of interconnected brain structures including the hippocampus, hypothalamus, thalamus, cortex, and mammillary bodies works in concert generating emotional states as well as associated conscious feelings (LeDoux 1996). An alternative model of emotion circuitry in the brain emphasizing the role of different brain areas was proposed in 1952 by Paul MacLean. Although, most of Papez’s or MacLean’s speculations did not stand the test of empirical verification, their intuitions that emotions and other functions are related to a coordinated activity of anatomically and functionally interrelated brain structures remained a common way of thinking in neuroscience (LeDoux 1996).

Significant progress in the neuroscientific study of emotion resulted when researchers focused on a particular class of emotions, such as fear or pleasure, instead of developing general purpose brain-based models for all emotions. In particular, studying fear and related brain structures provided new insights into neural mechanisms of emotions (LeDoux 1996).

In 1939, Heinrich Klüver and Paul Bucy observed that monkeys with severed temporal lobes did not express reactions associated with fear or anger (LeDoux 1996). Almost two decades later, in 1956, Lawrence Weiskrantz identified that the structure within the temporal lobe which lesions are associated with the Klüver-Bucy syndrome was the amygdala (LeDoux 1996). Subsequent research provided abundant evidence demonstrating the key role of the amygdala in emotions, especially in fear (LeDoux 1996; Phelps and LeDoux 2005). Receiving information from all sensory modalities, the amygdala is responsible for generating fear responses based on the processing of the sensory stimuli (LeDoux 1996; Phelps and LeDoux 2005). The information about natural threats appears to be evolutionary hardwired into animal brains. In contrast, learning and memory mechanisms in the brain enable acquisition and maintenance of the information about environmental threat experiences by an individual. If the stimuli are evaluated as threatening, the amygdala sends signals to the brain stem and hypothalamus, which further control fear defensive behaviors as well as associated physiological responses. Findings from animal research have been overwhelmingly supported by observations from human brain imaging studies showing the involvement of the amygdala in normal and pathological fear (Phelps and LeDoux 2005).

Animal research demonstrated that the sensory information reaches the amygdala through two independent inputs: the “low road” or thalamic pathway conveying rapid but imprecise signal and the “high road” delivering complex information from association areas in the cortex (LeDoux 1996). The “two roads” model of signal transmission explains why fear responses can be initiated (by the indirect “low road”) before we are aware of the eliciting stimulus (cortical association areas are implied in conscious processes). Human brain imaging studies demonstrate that the amygdala as well as fear responses may be activated by stimuli that are not consciously perceived (Phelps and LeDoux 2005). Although the amygdala circuitry is not the only structure

involved in fear, investigating the amygdala circuitry provided valuable insights into the ways the brain generates emotions.

Existing data demonstrate that brain systems involved in generating emotions are highly preserved throughout the evolution, e.g., even if differences in brain structure are taken into account, similar circuits are involved in controlling and generating fear in various species including fish, amphibians, reptiles, birds, and mammals, including humans. Emotional reactions, such as fear or anger, are evolutionally developed adaptive responses increasing individual chances of survival. Other emotions, such as disgust, guilt, joy, affection, pleasure, interest, etc., play their roles regulating various aspects of individual's psychological or social life (Dębiec 2007; Panksepp 1998). Emotional responses are in most instances generated unconsciously. They may be accompanied by conscious feelings when an animal has the capacity for conscious awareness (Damasio 2003; LeDoux 1996). Further research in psychology provided more evidence that affective and cognitive systems to a large extent may operate independently of each other (Zajonc 1980). Much work has yet to be done to further elucidate the relations between emotional responses and conscious feelings at the neural level.

The concept of empathy plays and has played an important role in contemporary and traditional discussions about the psychological mechanisms responsible for our ability to know other minds and our ability to be social creatures who are emotionally attuned to the feelings of others and who are also concerned about their well-being. While the concept of empathy is of rather recent vintage – it has only been coined at the beginning of the twentieth century – empathy-related phenomena have already been at the center of attention among Scottish moral philosophers of the eighteenth century, particularly David Hume and Adam Smith. They, however, referred to such phenomena by

using the term “sympathy.” Given the wide range of psychological phenomena that are collectively constitutive for our social abilities, both cognitive and emotional, it should maybe come as no surprise that the history of the empathy concept is characterized by a great deal of conceptual confusion and divergence. Readers of the literature on empathy are therefore well advised to pay very close attention to how exactly different authors conceive of empathy in order to properly adjudicate between their claims. In the following, this entry will broadly outline the various aspects of the empathy concepts and the associated debates.

The Concept of Empathy and Knowledge of Other Minds

Theodor Lipps (1851–1914) is appropriately regarded as the main source of the modern empathy concept or what he called “Einfühlung” (feeling into), since it was him who most systematically conceived of empathy as the central psychological mechanism allowing us to aesthetically appreciate works of art and objects of nature and who simultaneously also conceived of the very same mechanism as the basic and primary means for knowing others as minded creatures. Equally important, it was his conception that the American psychologist Edward Titchener referred to when translating the German term “Einfühlung” as empathy (Stueber 2006; 2008).

Lipps conceives of empathy as a biologically based resonance phenomenon. By nature, we are constituted so that we internally resonate with and mirror other persons’ mental states when we observe their activities or their bodily gestures. Nevertheless, in resonating with another person, we are also in some sense aware of the fact that we are merely vicariously sharing his or her thoughts or experiences. In resonating with your anger, we are also aware of the fact that it is not us but you who is really angry. We thus project our thoughts and experiences, which are caused by resonance, onto you. In this manner, Lipps suggested, empathy as inner resonance in the

perceptual encounters with others allows us to know what another person is feeling or thinking. Accordingly, for Lipps, knowledge of other minds involves processes of inner imitation and projection.

Lipps, however, did not regard empathy as one method among others for gaining knowledge of other minds. For him, it constitutes the only method since he thought of the ► [inference of analogy](#), which he regarded as the only alternative in this respect, as a conceptually inconsistent undertaking. It requires us to think of another person’s mind as something that is identical to my mind but at the same time also as something that is “absolutely different,” because it is something I do not directly experience (Lipps 1907).

Lipps’ writings were highly influential at his time. Yet philosophers did soon become concerned about whether empathy could be regarded as a reliable method of knowing other people’s mind as Lipps had claimed. Philosophers in the phenomenological tradition, such as Edmund Husserl, Edith Stein, and Max Scheler, generally accepted Lipps’s devastating critique of the inference of analogy as pointing to a fundamental shortcoming of the ► [Cartesian conception of the mind](#), which gives primacy to the first person perspective. Yet they asked why Lipps’s critique would not apply to his own conception of empathy since he still seemed to adhere to the general Cartesian framework of thinking about the mind. Phenomenologists continued to think of empathy as being central for our knowledge of other minds. Nevertheless, they did not conceive of it as a resonance phenomenon but as our unique ability to perceptually apprehend in a direct and non-inferential manner the mental states expressed in another person’s face, gesture, or even tone of voice (Zahavi 2010).

Lipps’s conception of empathy also resonated with hermeneutic philosophers concerned with the concept of understanding, which they regarded as the unique method of the human sciences. Yet while hermeneutic philosophers of the eighteenth and nineteenth century, such as Friedrich Schleiermacher, Johann Gustav Droysen, and the early Wilhelm Dilthey, did think of understanding to a large extent in

a psychological manner as involving rethinking and reexperiencing the mental life of others, philosophers in the hermeneutic traditions in the twentieth century wholeheartedly rejected a psychological conception of understanding and with it the concept of empathy. Particularly, Hans-Georg Gadamer argued that to think of understanding as empathy is epistemically naïve and simplistic. It does not sufficiently recognize that interpretation is always a holistic and culturally mediated affair whereby we understand individual texts and individual agency only by being able to situate them in a larger social and cultural context. Within the context of the philosophy of history, only the followers of the philosopher and historian Robin George Collingwood, like William Dray, for example, continued to defend empathic reenactment as the unique method of appreciating the thought processes of rational agents (Kögler and Stueber 2000; Stueber 2006).

Since the 1980s, empathy has become a topic of broad interdisciplinary research projects, a topic that has received renewed and sustained attention particularly from the neurosciences, but also from philosophy, developmental and social psychology, ethology, and even anthropology (Decety et al. 2009; Engelen et al. 2012; Coplan and Goldie 2011). Within the context of the contemporary ► [theory of mind debate](#), simulation theorists, who in contrast to theory theorists, argue that our ability to understand other minds is based on knowledge-poor mechanisms, again promote empathy or our ability to simulate the mental processes of others as a reliable means of knowing other minds. They generally distinguish between two levels in our simulative abilities. First, they postulate a cognitively and conceptually less complex and developmentally early capacity for making sense of others variously referred to as low-level mindreading or basic and mirroring empathy. Such basic level of making sense of other persons is seen as being neurobiologically realized by so-called mirror neurons, neurons that are activated both in the execution and the observation of goal-directed bodily movements or when feeling certain emotions and when observing others having

those emotions (Rizzolatti and Sinigaglia 2008). They also postulate a cognitively and conceptually advanced capacity of simulating the minds of others depending on our imaginative ability to take their perspective and look at the world from their point of view. Only on this level do we make sense of others in terms of our conceptually more sophisticated repertoire of folk psychological terms such as beliefs, desires, and so on and understand an agent's reasons for acting. Simulation theorists label this cognitively advanced level of understanding as reenactive empathy or more generally high-level mindreading (Stueber 2006; Goldman 2006).

Empathy and Moral Psychology

Empathy so far has been discussed primarily as a cognitive means for gaining access to other minds. Within the context of investigating the prosocial nature of human beings and the psychological foundation of moral agency, researchers however tended to conceive of empathy primarily as an affective phenomenon emphasizing our ability to vicariously share the emotions of others and to be emotionally attuned to their needs. While researchers did not always sufficiently distinguish between different dimensions of a human's affective attunement toward others, one nowadays generally distinguishes conceptually between four affective empathy-related phenomena, that is, emotional contagion, proper empathy, sympathy, and personal distress. Emotional contagion is referring to the human propensity to catch the emotion of others one associates with, such as the tendency to feel happy or panicky in a room full of happy or panicky people. Such propensity however does not involve the ability to recognize that one's happiness or panic has been caused by another person feeling a certain way. Proper empathy is referring to our ability to vicariously share another person's emotion (their grief or anger) and this also implies that we are in some sense aware of the fact that the felt emotion is more appropriate to the other person's circumstances than our own. Sympathy, on the other hand, does

not require that one shares the emotion of the other person. Rather it is a feeling of concern for the other person's well-being and accordingly it is an emotion *sui generis*, which is directed toward the other person. Finally, personal distress is an emotional reaction that is caused by the situation of another person while it is at the same time an emotion that is directed toward one's own self, such as when one feels upset about having to deal with the misfortune of another person when one really has better things to do.

Two comments are important in this context. First, given these conceptual distinctions, it needs to be stressed that human infants are able to experience proper empathy and sympathy only after they acquire the cognitive ability to sufficiently distinguish between self and other (usually in their second year). Second, while it is conceptually important to distinguish between these various affective phenomena, as a matter of fact they tend to occur together when humans encounter other persons, particularly other persons in need. Moreover it seems as if only creatures, which are receptive to emotional contagion, develop later on more mature empathic and sympathetic capacities. For this very reason, various researchers refer to sympathy also as empathic concern (Hoffman 2000; DeWaal 2006).

Affective empathy has been shown to contribute positively to prosocial behavior. With help of a number of ingenious experiments, Daniel Batson has also made a strong case for a causal connection between empathic concern or sympathy and the existence of genuine altruistic-motivation having the well-being of another person as its ultimate goal (Batson 2011). Yet he has also shown that we can be altruistically motivated to violate universal moral principles such as fairness and justice. In addition, it is commonly known that our ability to empathize and sympathize with others is limited and biased in that we tend to empathize more easily with others that in some sense are closer to us. It is exactly for this very reason that David Hume and Adam Smith in the eighteenth century thought that our natural ability for empathy, or what

they called sympathy, needed to be corrected and supplemented by the impartial spectator perspective in order for empathy to play a role as the foundation for moral judgments and for deriving universal moral principles. How exactly one should conceive of the contribution of empathy, in the cognitive or affective sense, as contributing to constituting us as social and moral creatures is therefore the subject of ongoing empirical research and continuous philosophical discussion (Coplan and Goldie 2011; Debes 2011; Slote 2010).

Empiricism

Carl Raschke
Department of Religious Studies, University
of Denver, Denver, CO, USA

A philosophical method first articulated by Francis Bacon in the late sixteenth century that shifts the focus of philosophical investigations, and overall the pursuit of science itself, from metaphysical speculation to immediate human experience, its testing, and evaluation. The early British “empiricists” emphasized “simple ideas” derived from sense observation over complex and grandiose philosophical concepts such as God, the universe, the soul, matter, etc. Later generations refined the principles of empiricism to involve mainly the formation of testable hypotheses and their validation through precise means of experimentation. The latter type of empiricism is now called the “scientific method.”

Endocrinology

Werner-Alfons Scherbaum
Heinrich-Heine-University Düsseldorf,
Düsseldorf, Germany

Description

Endocrinology is a biomedical discipline dealing with the origin, effect, and medical consequences of biochemical signals (hormones) that are transported via the blood stream to distant sites of the body to help communication between various organs and tissues. It is like sending email messages to the whole body via the blood. In that,

endocrinology has many similarities with neurology where nerve signals are transported via neurons and humoral neurotransmitters. As a clinical discipline, endocrinology deals with diseases of disturbed function – hormone excess and hormone deficit – and morphological pathologies of endocrine organs as well as diagnostic procedures, therapy, and management of respective diseases. As a science, endocrinology aims at understanding the basic mechanisms involved. Recently a major focus is on the understanding of the molecular mechanisms involved.

Neuroendocrinology describes the interaction between the central nervous system and endocrine systems in the control of homeostasis and its pathologies. For example, the cells of the neurohypophysis are originating from the brain and extend to the posterior pituitary gland from where – upon appropriate stimulation by peripheral or central signals – the antidiuretic hormone or oxytocin is released into the blood stream.

Self-identification

Science

Endocrinology is a clinical subject that tries to understand the physiology of endocrine regulation, to diagnose endocrine disorders and to treat and manage patients with such diseases. For the understanding of the physiology of the endocrine system and of the pathologies underlying endocrine disorders, the discipline takes advantage of chemistry, biochemistry, genetics, statistics, biometry, physics, biophysics, and other basic sciences. The advances in the subject in both clinical and basic endocrinology are driven by scientific methods, i.e., systematic research that allows to provide the clinical and scientific evidence required for appropriate diagnostic and therapeutic decision making. Evidence from published clinical trials as well as clinical observations and the experience of the physician are a basis for such decisions.

Comparative endocrinology clearly shows that the underlying mechanisms of communication between distant organs via fluids in a body are basic paradigms in the development of species.

We can now better describe how endocrine functions and species change in different habitats, such as the development of the water-saving principle of antidiuretic hormone in reptiles that first left the water. However, in most if not all other medical fields of endocrinology, we recognize and have to accept the limits of our knowledge and understanding whenever we try and dig deeper into the basic questions how the system exactly works and why it may get out of order in some cases at a certain time point.

Characteristics

Endocrinology is unique in its level of communication with many systems in the body. Distinct endocrine messages can be distributed to nearly all organs within a short time, and negative or positive feedback regulation is a common feature of endocrinology. The same hormone may have various effects in different organs of the body since the perception of such a signal is dependent on the presence of specific receptors in the recipient cells. The interaction between the ligand and the receptor, and the appropriate triggering of the recipient cell machinery drive the response of the recipient organ and also the endocrine feedback response that is not only provided to the signaling endocrine organ but may also extends to other organs of the body.

Relevance to Science and Religion

The discipline endocrinology does not see itself as relevant to the scholarly area “Science and Religion.” However, many processes in endocrinology are too complex to be fully understood so that we just have to accept them as a fact and describe them as they are, with a scientific strive to find out the origins which we will probably never be able to indicate [1, 7].

Sources of Authority

The word hormone was first coined in 1905 by Ernest Starling (1866–1927) from University

College London who had first discovered the hormone secretin in 1902. The term “hormone” was soon universally accepted [10]. However, there were a number of researchers who had already discovered the principles of endocrinology before that time. Performing a series of experiments, the German anatomist and physiologist Arnold Berthold (1803–1861) working in Göttingen was able to show that the secondary sex characteristics of castrated cockerels could be maintained by implanting the testes to other places and he was able to prove that this was mediated via the bloodstream [6]. In 1855, the physiologist Claude Bernard (1813–1878) from Paris described that glucose synthesized in the liver was secreted into the portal vein, and he thus provided direct evidence for internal secretion. Thomas Addison (1793–1860) from Guy’s Hospital in London described the function of the adrenal glands. Addison’s disease is a complete failure of the adrenal cortex and is lethal when untreated. It was only in 1948 that an extraction and synthesis of the adrenocortical hormone cortisone was achieved and was applied as a life-saving drug in patients with adrenocortical insufficiency. This work was honored with the Nobel Prize to Kendall, Reichstein, and Hench. The most prominent patient with Addison’s disease was John F. Kennedy, the former president of the USA. In 1911, Walter Cannon (1871–1945) described that fear or anger leads to a release of the hormone adrenaline from the adrenal medulla.

Similar developments can be seen along the discovery of insulin [2]. The German pathologist Paul Langerhans (1847–1888) first described the pancreatic islets. Later in the century Joseph von Mering (1849–1908) and Oskar Minkowsky developed a deeper understanding that diabetes mellitus was associated with the pancreas and Gustave-Edouard Languesse (1861–1927) demonstrated that the endocrine pancreatic secretions are to be distinguished from the action of the exocrine acini. It was only in 1921 when insulin could be extracted from the pancreas by John Macleod (1876–1935), James Collip (1892–1965), Sir Frederick Banting (1882–1941), and his student Charles Best

(1899–1978) from the University of Toronto. For this achievement, Banting and Mcleod got the Nobel prize, but Banting shared it with Best, and Mcleod shared it with Collip who was the brain behind all this work. In 1922 the so-called isletin was first injected into the blood of wasting children with diabetes and was able to save their lives. In 1923, the industrial production of insulin was taken up by Eli Lilly in the USA, and in the same year, insulin production was licensed by Hoechst in Germany.

A number of further endocrinologists and pioneers in medicine were awarded with the Nobel Prize, such as Emil Theodor Kocher (1841–1917) for his work on the thyroid gland or Rosalyn Yalow (1921–2011) who obtained the Nobel Prize 5 years after the death of Solomon Berson (1918–1972) with whom she had first described the radioimmunoassay (for the measurement of insulin). There are other great pioneers who were, however, not awarded with the Nobel Prize such as Deborah Doniach (1912–2003) and Ivan Roitt (b.1927) from the Middlesex Hospital London who were the first in 1956 to describe autoantibodies to thyroid microsomes and thyroglobulin that are a key feature of autoimmune thyroiditis. Deborah Doniach was a leading figure in modern immunology opening the concept of autoimmune disease.

In 1986, Pierre Marie (1853–1929) described acromegaly (Pierre Marie’s disease), and it was later realized that both acromegaly and gigantism were associated with pituitary tumours.

In 1912, Harvey Cushing (1869–1939) described the close relationship between pituitary tumors and certain syndromes, and in 1932 he described the basophil tumor that was later called Cushing’s disease [3].

The field of neuroendocrinology is closely linked with the pioneering work by Ernst (1905–1965) and Berta Scharrer (1906–1995) who recognized that neurons in the hypothalamus are the source of the axons that constitute the neurohypophysis [9].

Andrew Schally and Roger Guillemin with their groups elaborated that the anterior pituitary is tightly controlled by the hypothalamus and in a

historic race for the first description they isolated the relevant peptide-releasing hormones. Both of them were jointly awarded the Nobel Prize in physiology or medicine in 1977 [4, 8].

Ethical Principles

Endocrinology deals with many subjects where ethical considerations are key issues. These are, among others, reproductive medicine, transsexuality, diagnosis of diseases in utero, abortion, and preventive medicine in endocrine disorders related to gene aberrations. For most of these issues, the endocrinologists discussed the matter thoroughly and published recommendations for the clinicians and also for health providers and political decision makers. For example, inherited C-cell carcinoma is a genetic trait with such a high penetrance that it is recommended to completely remove the thyroid gland in childhood in order to prevent the cancer to grow and to set metastases. It is well understood that this involves a high responsibility of the doctors involved in the diagnostic and preventive procedures that may also set the individuals at risk.

Key Values

Endocrinology considers the body as a whole as well as the communication between different organs. It also considers the communication between the body and the environment, for example, in the expression of hormonal responses to environmental stress.

Conceptualization

Nature/World

Nature and the world can be seen as a system of homeostasis and eruptions. These are also key issues in endocrinology where basic hormone secretion is regulated by many factors that aim at achieving a balance of the whole system. To achieve a homeostasis, the hormonal system has

a wide array of regulatory mechanisms such as the negative feedback systems. On top of that eruptions of hormones occur mostly in a meaningful way, for example, the mid-cyclic surge of luteinizing hormone that induces ovulation.

Human Being

Endocrinology is closely linked with the processes of mating, conception, growth, puberty, maturity, and senescence which are rather features of most animal species than of human beings. These close links with other species are important unifying factors that reconcile human beings and biology. These important links are studied in the field of comparative endocrinology.

Life and Death

Endocrinology is a system of higher developed life. Programmed cell death (apoptosis) of certain cells is a prerequisite of life and development of organs including endocrine glands. Even in adults ontogenic regression with programmed reversal of reproductive maturation and function may occur during states of acute systemic illness and may be reinstated when the prevailing environment is more favourable [5].

Reality

In endocrinology, most values are not absolute but relative to others, so that the reality is always to be seen in relation to the actual situation. For example, the same cortisol value in the blood may be too high or too low, depending on the clock time we look at it.

Knowledge

Knowledge in endocrinology is a combination of objective accumulation of knowledge, and insight based on clinical experience.

Truth

In endocrinology, facts are considered as true when they are based on clinical or experimental scientific evidence as well as personal experience. For example, the reduction of the number of storks in the Alsace definitely coincides with a reduction of the birth rate but this does not necessarily mean that the storks provide our babies.

Perception

Why do men feel as men and women as women, and why do some women with all the hormonal signs of women feel as men and vice versa. When and where does the sexual programming take place and what is going wrong in the exceptional cases? How do psychological and psychosocial events influence the hormonal homoeostasis and vice versa?

Time

Cyclic processes are immanent to endocrinology, for example, cyclic secretion of hormones with short cycles such as the 90 min peaks of gonadotropin-releasing hormone, the daily rhythm of cortisol secretion, the light-induced release of melatonin, or the monthly menstrual cycles in women. The regulation of clock genes is a fascinating issue underlying these processes on a molecular level.

Consciousness

It is increasingly recognized that endocrine hormones are not only regulated within the endocrine system but they also influence brain functions and psychological activities such as consciousness.

Rationality/Reason

Psychiatric manifestations of endocrine disorders may be elicited by excessive derangements of various hormones. This clearly shows that clinical symptoms of endocrine disorders cannot be completely explained by the known hormone actions.

Mystery

There are plenty of mysteries in endocrinology. It is a general feeling and probably a fact that mysteries turn up at any edge of our scientific achievements, thus pushing further scientific work which leads us to a higher level of knowledge and to mysteries at a higher level.

Introduction

The concept of energy has a fundamental place in physics – a place that was acquired in the

nineteenth century when its emergence provided a new and unifying framework bringing together all known phenomena within the dominating mechanical view of nature and embracing heat, light, and electricity, together with mechanics, in a single conceptual structure (Harman 1982, p. 2). This new framework led to the development of the concepts of the physical field, electromagnetic ether, conservation and dissipation of energy which, in the beginning of the twentieth century, opened the way to the formulation of the theories of relativity, quantum mechanics, and gravitation. The evolution of these theories still governs our knowledge about the structure of matter, about the world and the cosmos. Yet, the obvious relevance and pervasive use of the concept of energy in physics did not stop Richard Feynman (1918–1988, recipient of the Nobel Prize in Physics in 1965) to write that: “It is important to realize that in physics today, we have no knowledge of what energy ‘is’ (Harman 1982, p. 4-2).”

The Concept of Energy in Classical Physics

The discussion of the concept of energy usually starts with an emphasis on mechanics, but it is only to go beyond it. According to Eugene Hecht “... it influences our thinking about every branch of physics, indeed, about every aspect of our existence. Yet, there is no completely satisfactory definition of energy. Even so,” he continues, “we will quantify its various manifestations as we struggle to define it (Hecht 2000a, p. 222).” In its most popular meaning, the concept was used at least since the late 1500s and was associated with the capacity of physical objects and systems to do work. In 1638, Galileo employed the term *energia* though he never defined it. It was only in the 1850s that the idea had taken on a scientific meaning – a meaning that is not altogether satisfactorily defined. “In very general terms, energy describes the state of a system in relation to the action of four forces” (Hecht 2000a, p. 223) – gravitational, electromagnetic, strong and weak. It is therefore a relational

concept, a concept which is inherently associated with the description of motion, change and the interaction between physical objects and systems in general.

Energy and Change

Energy is a property of all matter and is observed indirectly through changes in physical objects’ speed, mass, position, and so forth. The change in the energy of a system, which is all we can ever measure in an experiment, is a measure of the physical change in that system. Force is the agent of change, whereas energy is the measure of change. Because a system can change through the action of different forces in different ways, there are several distinct manifestations of energy.

By observing the changing behavior of matter, we ‘infer’ the presence of one form or another of energy. Still, energy is not an entity in and of itself – there is no such thing as pure energy. Energy is always the energy of something. The concept of energy provides a means of quantitatively accounting for physical change. When a material system manifests an observable change due to some interaction, we associate an amount of energy with the extent of that change. Interaction is crucial; if matter did not interact, the concept of energy would be superfluous. (Hecht 2000a, p. 223)

Mario Bunge points out that, since it is ubiquitous, the concept of energy must be philosophical and, in particular, metaphysical belonging in the same league as the concepts of thing and property, event and process, space and time, causation and chance. He identifies energy with changeability (Bunge 2000, p. 458).

Kinetic and Potential Energy

It is interesting to point out that the concept of energy is associated with the concept of work. This association makes a lot of sense given the semantic meaning of the word *energeia* in Greek which comes from *energos*: *en* – “at” + *ergon* – “work.” In mechanics, work is defined by the product of force and distance, and happens to be equal to the change of energy resulting from the application of that force to a body as that body moves through a distance in space. This type of energy is naturally associated with motion and is

called *kinetic energy*, a term introduced by Lord Kelvin (William Thomson) in 1849. It was defined as the square of the velocity v of an object multiplied by its mass m divided by two: $mv^2/2$. If, however, the force acting upon the body is naturally present after its displacement and the body is kept motionless but potentially susceptible to the force action, the potential for generating the kinetic energy is still there because of the presence of the force. This type of energy is known as *potential energy* and exists by virtue of the position of the body in relation to a naturally present force. Such is the situation when the gravitational force causes the free fall of objects which are left on their own without any support at some height above the surface of the earth. In summary, kinetic energy is associated with the capacity to do work by virtue of motion; potential energy is associated with the capacity to do work by virtue of position.

Energy Conservation Law and Symmetry

R. B. Lindsay defines the concept of energy through the concept of change pointing out, however, that the basis of its usage today is the idea of *invariance*, which means constancy in the midst of change (Lindsay 1971, p. 384; 1972, p. 219). Lindsay's shift of focus from change to invariance alludes to the energy conservation law – the empirical fact that, whenever an amount of energy is transferred from one entity to another, the total amount of energy always remains unchanged. This shows that “the importance of energy springs not just from its variety of form, but from its conservation: the total amount of energy in the cosmos remains always the same, since the loss of one kind of energy is always being compensated by the gain of another kind of energy (Word 2005, p. 18).” It is important to note that the conservation of energy applies to systems and not to individual bodies. The total energy of a system of bodies includes contributions from both, kinetic energy of motion, and potential energy that reflects the interaction between the bodies. The potential energy contributions depend on the distances between the bodies, their electrical charges, and, possibly, other things. It is only the total energy that is conserved.

Conservation laws are commonly considered as the deepest and most significant types of scientific laws because they give insights into the symmetry of the physical systems but, more importantly, into the symmetries of space and time (space-time). More involved mathematical manipulations of the classical physics laws of motion reveal that energy conservation stems from the “smooth” nature of time, i.e., from the fact that “it spreads smoothly from the past into the future with no squashed bits or stretched bits” (Atkins 2003, p. 98). What this really means is that the energy conservation law could be mathematically derived from the invariance of the physical laws to forward and backward time changes. So deep is the relationship between conservation laws and the symmetry of space-time that the conservation laws survive even when classical physics laws of motion fail and there is a need to move into the realm of relativity and quantum mechanics. This relationship shows that the stability and the sustainability of the physical world are deeply rooted into the symmetry principles of its most fundamental inner structure (Atkins 2003, p. 98).

From Visible to Invisible

Historically, the concept of kinetic energy was introduced first. The introduction of potential energy provided continuity to the idea of energy in general since its change was associated with the work done on a body against a naturally present external force. Its relevance to the development of physics was found to be critically important:

The concept of kinetic energy, as it stands, is a derivative concept since it is directly definable in terms of observables, namely mass and velocity. To this extent its usefulness is limited, and it affords no deeper understanding of the nature of mechanical systems; its logical distance from observation is too slight. But the value and significance of the concept are immeasurably increased, both for mechanics and as it turns out for physical science as a whole, by the introduction of the additional concept of potential energy. This move at one stroke places energy among the most important of physical concepts. The new notion of energy thus created, represents a considerable conceptual sophistication of the old one; its logical distance

from observation is now very much greater, and the concept casts its net more widely. (Theobald 1966, p. 39).

It is, therefore, the logical distance from observation that provided the concept of energy its metaphysical relevance. It is the shift from the description of the visible properties of physical objects and systems to the manifestation of their invisible ones that makes it universally meaningful.

Energy and Fields: The Electrical Field as an Example

The relevance of the concept of potential energy is inherently associated with the emergence of the field concept. To clarify what a field is, we could use an example from electrostatics – the part of physics dealing with electrical charges, fields, and their interactions. The concept of electrical charge is fundamental and cannot be described in simpler, more basic concepts. In the words of Eugene Hecht: “We know it by what it does and not by what it is – if you like, it is what it does, and that’s that (Hecht 2000b, p. 610).” A charged particle such as the electron interacts with other charged particles by creating a web of interaction around itself that extends out into space. We say that one charge creates an electric field in space and when another charge is immersed in that field, it interacts directly with it. The field that surrounds an electrical charge is part of it and becomes the media or mediator of the interaction with the other charge. The picture is quite straightforward, but raises many questions. The main question is why do we need the field concept? The answer is: to deal with the explanation of “action at a distance,” and the principle of “locality” – the expectation that effects must be co-located with their causes, both in space and in time. One electron causes another, second, electron located at some distance away, to experience a certain force. This force seems to have no cause located any nearer to the second electron than the distance to the first one. It seems, therefore, that there is no visible local cause for the force experienced by the second electron. The introduction of the field concept by Michael

Faraday enabled electric interactions to satisfy spatiotemporal locality and explain the action at a distance, i.e., that the electric force acting on a charged body at a given moment in time is caused by the electrical field at its location. The field is invisible, but it becomes visible by its effects. Its energy is manifested by the work done by the electrical field force for moving the charge away at a given distance. Even this simple exposition of the field theory clearly shows in what sense the concepts of energy and field are interrelated. Energy “becomes the basic ‘substance’ of field physics, as matter was the basic ‘substance’ of Newtonian physics. Energy is not a way of characterizing particles, but a way of characterizing processes in the field” (Theobald 1966, p. 50). “It is so because the field is characterized by the presence of energy. . . . A field is nothing more than a spatial distribution of energy which varies with time. Energy has thus been freed from its dependence upon physical vehicles such as particles; it has achieved the status of independent scientific existence” (Theobald 1966, p. 98).

How should we interpret then the comment of Richard Feynman that in physics today, we have no knowledge of what energy *is*? In his comment Feynman continues as follows: “We do not have a picture that energy comes in little blobs of a definite amount. It is not that way. However, there are formulas for calculating some numerical quantity and when we add it all together it always gives . . . the same number. It is an abstract thing in that it does not tell us the mechanism or the reason for the various formulas. . . . Conservation of energy can be understood only if we know the formula for all of its forms” (Theobald 1966, p. 4-2). Such an approach to the definition of energy is an example of operationism – the view that the meaning of every scientific term must be specifiable by identifying a definite testing operation that provides a criterion for its application. This means, unfortunately, that for most physicists “the whole of physics is about operations, chiefly measurements and computations, rather than about nature” (Bunge 1973, p. 1).

The Concept of Energy in Modern Physics

Energy in Quantum Physics

Max Planck and the Quantum of Energy and Action

The idea of the quantum of energy was introduced as a kind of energetic atomism, in which energy could not be divided into arbitrarily small amounts but existed as discrete, tiny packets (Dear 2006, p. 142). In its origins, the introduction of the concept of energy quantization was driven by deeply practical reasons. In 1900, it allowed the German physicist Max Planck to create an adequate mathematical model of a troubling problem – the so-called black-body radiation, i.e., the radiation that is emitted by a specific type of heated bodies. Planck worked with careful experimental measurements of the actual energy distribution trying to develop a correct theoretical model to describe it. Eventually, he found out that he could do that only if he assumed that the emitted energy could change only in jumps, from one energy level to the next. This assumption in Planck's model violated the usual way of thinking about energy – as a quantity that could vary smoothly, increasing or decreasing gradually, rather than being confined to stepwise change. Some people consider Planck's assumption as a “desperate” but the only possible move enabling him to fit the empirical data on black-body radiation. Planck called these discrete energy changes “quanta” of energy. He assumed that their necessity in the theory would soon be explained, and that the explanation would not require energy itself to exist only in bundles of specific sizes. He, however, was not able to come up with such an explanation himself.

The Universal Meaning of the Energy Quantum Concept

Very soon other physicists began to see the more universal meaning in Planck's idea. In a paper of 1905 focusing on the photoelectric effect, Albert Einstein argued that light itself should not be understood simply as wave motion but should also be understood in terms of light quanta – massless

packets of energy that were later to be called “photons.” The energy of a single photon E was found to be proportional to the light's frequency ν : $E = h\nu$. The constant h was first derived by Planck and, therefore, known as Planck's constant or the “quantum of action.” Soon after the emergence of the photon, the idea of the quantum nature of energy was extensively infiltrated into microphysics.

In 1913, the Danish physicist Niels Bohr opened up a critically important new arena for the use of the concept – atomic spectroscopy. It was the exploration of this arena that led to the emergence of quantum physics. Bohr adopted Planck's quantum to study the internal structure of atoms in a way that was “in obvious contrast to the ordinary ideas of electrodynamics but appears to be necessary in order to account for experimental facts” (Dear 2006, p. 144). He started with the commonly accepted “solar system” model of the atom wherein negatively charged electrons orbit around the central positively charged nucleus like planets. “The size of an electron's orbit corresponded to the orbit's energy, and Bohr postulated that the only orbits permitted to such electrons were those whose energy corresponded to discrete, quantized levels – not just any amount of energy, or orbit, was allowed by his model. There were levels, or steps, of orbital energy that the electrons could occupy; Bohr called them ‘stationary states.’ The only changes in orbital levels that an electron could undergo were ones in which it shifted, in a discrete jump, from one stationary state to another” (Dear 2006, p. 144). Assuming the discrete nature of these changes allowed Bohr to interpret some of the experimental results that had been known for nearly 30 years. These results concerned the radiation emitted by hydrogen atoms when excited by heat. When the radiation was separated out according to frequency by a spectroscope, the spectrum showed a series of discrete bright lines that was uniquely related to the specific internal structure of hydrogen atoms. Even though quantum theory was still in its initial stages, there was a major epistemological breakthrough that was associated with Niels Bohr's

achievement – the demonstration that the energetic manifestations of light quanta could be identified with the composition of atoms and the structure of matter in general. The dynamic structure of matter is manifested or known by the particular mode by which the smallest quantities of energy are presented to the observer.

Quantum Versus Classical Energy

One of the most obvious and important differences between classical and quantum physics is that the exchange and transformation of energy is not regarded as a continuous process. In classical physics, the use of the energy concept is process driven and descriptive in nature. It presupposes continuity and needs to be abandoned when moving into the realm of quantum physics (Theobald 1966, p. 117). But concepts such as conservation of energy which do not require following the actual process of change are still naturally valid in quantum theory. In other words, the radical newness of quantum theory is associated with the way it describes the states of systems and has nothing to say of the processes by which states of affairs are realized. This does not mean that nothing ever happens; it simply means that continuous processes escape the conceptual apparatus of quantum theory. This “new” physics deals with the energetic manifestations of physical realities, which are invoked or actualized in acts of observation performed in a way suitable to the dynamics of their inner nature (Wilczek 2008, p. 74). Quantum objects are not only invisible but also unimaginable, i.e., the fundamental concepts of quantum physics are not accessible to human imagination. This leads to a continuous need of interpretation. Such an interpretation could happen only within the framework of activities of a given scientific community driven by its historically developed ontological and epistemological presuppositions.

Energy in Relativity and Cosmology

Special Theory of Relativity and $E = mc^2$

The special relativity of Einstein came out of the study of electricity and magnetism. It arose from a description of the world based on the concept of field. As we have seen, fields are physical realities

filling all space and mediating the interaction between physical particles such as electrons, protons, and neutrons. This was a world different from Newton’s world that was based on particles exerting forces on one another through empty space. The insights of special relativity, however, go far beyond electromagnetism since its essence is rooted in a symmetry principle – that the laws of physics should take the same form after an increase of the velocity of all objects by the same constant value. What Einstein really did was to change Newton’s laws of classical physics of motion so that they obey the symmetry principle found in electromagnetism.

The first of Einstein’s insights about the concept of energy was the association of mass with energy: “One more consequence of the electrodynamical paper has also occurred to me. The principle of relativity, together with Maxwell’s equations, requires that mass be a direct measure of energy contained in a body; light transfers mass. . . . The argument is amusing and attractive; but I can’t tell whether the Lord isn’t laughing about it and playing a trick on me” (From a letter to Conrad Habicht in 1905). Einstein obviously talks about his famous equation $E = mc^2$ which holds for isolated bodies at rest (m is the mass of the body and c is the speed of light). For moving bodies, the correct mass-energy equation becomes $E = \gamma mc^2$ and includes an additional factor $\gamma = 1/(1-v^2/c^2)^{1/2}$ which depends on the velocity of the body v . Einstein’s result implied that the mass of any body was equivalent to its energy at rest.

“Energy of Being”

The message coming from the equation $E = mc^2$ was rather radical – the concept energy associated with physical particles is not necessarily related to motion (kinetic energy) and positioning (potential energy), “. . . there is also an energy that a particle has from its mere existence, an energy that depends directly on the mass” (Feynman 1994, p. 65). Therefore, in the world of isolated elementary particles “there are two significant forms of energy: the mass energy and the kinetic energy of motion. The mass energy of a particle is its energy of being”

(Word 2005, p. 18). Energy of being is proportional to mass. “Twice as much mass means twice as much energy, and no mass means no energy. . . . So mass represents a highly concentrated form of energy” (Word 2005, p. 19). It took many years before Einstein could assume in 1932 that his equation $E = mc^2$ was experimentally confirmed and it is now well known that it is correct.

Energy, Gravitation, and the Geometry of Space-Time

The second of Einstein’s insights about energy is related to his theory of gravitation. After the development of the special theory of relativity, Einstein started looking for a way to include gravity into the new framework and, in the end, produced a field-based theory of gravity – general relativity. The fact that general relativity is a field theory should be of no surprise. One of the main insights from the special theory of relativity was the postulate that the velocity of light, c , is constant but, even more importantly, limited. Therefore, the influence of one particle to another cannot be transmitted faster than that. Newton’s law of the gravitational force did not obey that rule and was not consistent with special relativity theory. General relativity arose as an update of Newton’s gravitation theory by fixing this inconsistency with the help of a field-based approach. Using the relativistic principles, Einstein showed how energy creates a gravitational field playing the role that was previously occupied by mass alone. In his gravitation theory, Einstein related the metric or the curvature of the geometry of space-time to the strength of the gravitational field arising from any energy present, showing that gravity could be deeply encoded in the geometry of space-time. Mass and energy distort space-time, and the distorted space-time in turn accounts for gravitational effects on matter and energy (for example light) moving through it.

Matter, Dark Matter, and Dark Energy

The third of Einstein’s insights about energy is related to cosmology. In 1917, based on his two initial insights, Einstein derived the set of equations describing the metric of the space-time of

the universe as a whole. He thought that the universe had a constant density in time and space but eventually found out that there is no solution with those properties. To get the constant density solution, Einstein added to the equations for gravity a new term called the “cosmological term” or the “cosmological constant.” The solution he found corresponded to a closed static universe – a big sphere with finite radius that stayed constant over time. This solution happened to be unstable. In addition, in 1929, Edwin Hubble provided convincing evidence that the universe is in fact expanding, leading Einstein to admit that the introduction of the cosmological term was his “greatest mistake” or “blunder.” Nevertheless, the possibility he identified, of adding a new term to the equations of general relativity to describe the universe, did not go away and became a matter of serious study in the following 70 years. Cosmological observations remained consistent with a cosmological constant equal to zero until about 1998, when convincing measurements began to indicate that there is indeed an accelerating cosmic expansion that could be explained by the presence of a cosmological term with a cc having a very small positive value. Subsequent observations provided additional support for this and Einstein’s introduction of the term in 1917, although introduced for the wrong reasons, was found to be prophetic.

The cc or the cosmic density was recently estimated by measuring its effects on the curvature of space through the distortion such curvature causes in images of distant galaxies (Wilczek 2008, p. 108). It is a powerful new technique measuring some of the properties of the cosmic microwave background radiation (CMB). Using this technique, by 2001, several groups made several important conclusions. First, the universe is made up of 30% matter. Second, only 5% of these 30% is the matter as we know it – the kind of matter we study in biology, chemistry, engineering, and geology and the kind of matter we are made from. The remaining 25% is a special type of (dark) matter – it is not uniformly distributed in space and its density is not constant in time. Observations suggest that it is based on

a special (probably new) particle, but it is not clear what this particle is. The new Large Hadron Collider (LHC) in Geneva is expected to help in identifying the source of dark matter. Third, there is a 70% missing component which is not matter and which is considered as being contributed by the so-called dark energy. It appears to be very uniformly distributed in space and time and has been observed only through its gravitational influence on the motion of normal matter. This makes it look like a property of empty space. It has not been observed to absorb light, i.e., it is not dark in the usual sense but transparent. The dark energy concept is directly associated with Einstein's cosmological term – although there are slight differences in the interpretation, they may refer to the same physical phenomenon (Wilczek 2008, p. 105). “The theory of dark energy is in bad shape. It's a problem for the future” (Wilczek 2008, p. 195). The current guesses are that it is some sort of force field which permeates the vacuum but there is no currently known theory of physics that could explain it. On the other hand, “the dark-matter problem, . . . , is ripe for solution” and there are promising ideas that could explain what dark matter is (Wilczek 2008, p. 196). Some physicists believe that, with the addition of his cosmological term, Einstein had in fact identified a new form of energy that is associated with space-time itself – it is not carried by matter and not the result of the known forces, i.e., a kind of vacuum energy. This is the first time in physics when a new form of energy is identified together with a claim that there is nothing carrying it. There are two other logical possibilities. Either we are now seeing the effects of some new substance that was not previously seen before, or there is something wrong with our current theoretical worldview (Taylor 2008, p. 41).

The Concept of Energy within the Context of Religion

The concept of energy is often considered within the context of specific religious worldviews.

One of the most representative examples can be found in Eastern Christianity where the distinction between essence and energy has been playing a significant role since the fourth century A.D. This last section will briefly focus on the concept of energy in Eastern Christian theology (Tanev 2009).

It was probably St John of Damascus (c. 676–749) who defined it in a most straightforward way:

... energy is the natural force and activity of each essence: or again, natural energy is the activity innate in every essence: and so, clearly, things that have the same essence have also the same energy, and things that have different natures have also different energies. For no essence can be devoid of natural energy. . . . Natural energy again is the force in each essence by which its nature is made manifest. And again: natural energy is the primal, eternally-moving force of the intelligent soul: that is, the eternally-moving word of the soul, which ever springs naturally from it. And yet again: natural energy is the force and activity of each essence which only that which is not lacks. (John of Damascus 2000, Writings, “Concerning Energy,” *Orthodox Faith*, Book II, Chapter XXIII)

One of the key aspects of the definition is the universality of the distinction between essence and energy: “of each essence,” “in every essence,” “no essence can devoid of natural energy.” St John of Damascus makes a careful distinction between four related terms:

But observe that energy and capacity for energy, and the product of energy, and the agent of energy, are all different. Energy is the efficient and essential activity of nature: the capacity for energy is the nature from which proceeds energy: the product of energy is that which is effected by energy: and the agent of energy is the person or subsistence which uses the energy. Further, sometimes energy is used in the sense of the product of energy, and the product of energy in that of energy, just as the terms creation and creature are sometimes transposed. For we say ‘all creation,’ meaning creatures. (John of Damascus 2000, Writings, “Concerning Energy,” *Orthodox Faith*, Book II, Chapter XXIII; Book III, Chapter XV, “Concerning the energies in our Lord Jesus Christ”)

This text was used as a reference for the criterion of Orthodoxy used during the Byzantine

Church Council in Constantinople, 1351. The Council confirmed the orthodoxy of the theology of St Gregory Palamas (1296–1359) – a monk of Mount Athos in Greece and later the Archbishop of Thessaloniki who became known as a preeminent theologian of the Divine energies (Kapriev 2005). The distinction between essence and energy in God is the fundamental epistemological premise of the theology of St Gregory Palamas:

With respect to the fact of its existence but not as to what it is, the substance is known from the energy, not the energy from the substance. And so, according to the theologians, God is known with respect to the fact of his existence not from his substance but from his providence. In this the energy is distinct from the substance, because the energy is what reveals, whereas the substance is that which is thereby revealed with respect to the fact of existence. (Palamas 1988)

For Palamas, the energy differs from the essence but is not separated from it. The essence refers to the immanent, self-identical being of God, while the energy means that God does something and He does it willingly. The energy does not denote something other in God than His essence but is the same Divine being as active *ad extra* (Tollefsen 2008, p. 141). This activity *ad extra* includes God's works such as creating, sustaining, providing, deifying, etc. "When the activity is spoken 'objectively' as a divine work (*ergon*) or being, ... we are not to imagine a something existing between the divine essence and creatures. The terms work and being denote, ..., the reality of God's activity as a powerful presence (Tollefsen 2008, p. 141)." God's works represent his activity or energies in relation to His creatures and God, as He is in Himself, should be distinguished from God as He related to something other than Himself. The Divine energy is what manifests that God is, while the essence is what He is. If there was no distinction between Divine essence and Divine energy, the fact that "God is" would have remained unknown. The focus here is on the knowledge of God, i.e., the distinction between essence and energy and the meaning of energy itself is articulated within an entirely epistemological context.

It is important to underline the personal dynamic nature of the Divine energies. Although God affects things and persons on each occasion through a particular energy or operation, it is always Him personally acting and wholly present in it:

The operations which produce the attributes of the world are, therefore, bearers of certain attributes found in God in a simple and incomprehensible way. The operations, therefore, are nothing other than the attributes of God in motion – or God Himself, the simple One, in a motion which is, on every occasion, specific, or again, in a number of different kinds of motion, specified and unified among themselves. God Himself is in each of these operations or energies, simultaneously whole, active, and beyond operation and movement. ... We only know the attributes of God in their dynamism and to the extent that we participate in them. ... we only know them through the prism of the effect they produce in the world. God Himself changes for our sake in His operations, remaining simple as the source of these operations and being wholly present in each one of them. (Staniloae 1998, pp. 125–126)

The nature of the Divine energies cannot be grasped except dynamically and as a result of God's personal activity and will. It is exactly this Divine personal dynamics that makes the invisible God visibly present in the world. In a way similar to the situation in quantum physics, these dynamic personal (hypostatic) presence and manifestations cannot be considered apart from us. We are co-participants to the measure of our personal cooperation which is borne within the specific context and status of our own spiritual "devices" and sacramental life.

One could summarize therefore that the meanings of the concept of energy in Orthodox theology and physics intersect at the epistemological level. The similarities are definitely more visible in relation to quantum physics, the theory of relativity, and cosmology than in relation to classical physics where the concept plays a more descriptive than epistemological role. In both cases, orthodox theology and quantum physics, the concept deals with the articulation of the hypostatic manifestations of the realities which are invoked or actualized within the

experiential acts of Divine-human and object-instrument interactions. The hypostatic nature of the energetic manifestations in physics is expressed by the fact that energy is always associated with something – a physical entity, such as particles, bodies, fields, or a physical system. There is one single occasion in physics where there was a claim about the existence of a kind of vacuum energy or energy of “nothing.” This is the so-called dark energy in cosmology which is believed to be associated with space-time itself and which is not carried by any known fundamental particle. This belief, however, appears to be more of a speculation. The fundamental difference between the two concepts is rooted in the different nature of the realities they are dealing with and can be expressed as the difference between “created” and “uncreated,” “person” and “thing,” “personal” and “impersonal.” The Divine realities are the dynamic personal realities of a living and loving God Who has a will. God does what he wants and human spiritual efforts make sense only within the context of a personal relationship with Him.

Enlightenment

Sharon L. Coggan

Department of Philosophy, University of Colorado Denver, Denver, CO, USA

In this context, it refers not to the experience of awakening as in the Buddha's enlightenment, but rather to an era in European history, beginning in the last half of the eighteenth century.

The era represented a paradigm shift in European culture that elevated the light of Reason as the best tool for determination of what is true and valuable. The Enlightenment era produced a challenge to the ancient regime in politics and culture. It celebrated the new ideals of egalitarianism, fraternity, liberty, freedom of speech, assembly, religion and the principle of democracy, and self-government. In Religious Studies, the Enlightenment era produced the foundational norms in scholarship and academic investigation of the subject of religion.

Environment of Evolutionary Adaptedness (EEA)

Matt Rosano
Psychology Department, Southeastern Louisiana
University, Hammond, LA, USA

The natural habitat or environment to which humans were originally adapted. This is assumed to be the hunter-gatherer lifestyle and habitat where humans spend over 99% of their evolutionary history. However, it must be recognized that each adaptive trait has its own unique evolutionary history and therefore its own particular EEA. For example, the human fear response is particularly sensitive to signals associated with the presence of snakes and spiders. This reflects the fact that these threats were prevalent in the ecological environments of our ancestral past. Human reasoning, however, exhibits characteristics reflective of the social environment of the past, where concerns about cheating on social agreements would have been of particular concern. So while both of these adaptations reflect elements of our hunter-gatherer origins, they reflect different aspects of those origins: one ecological, one social.

Environmental Ethics

Christopher J. Preston
Department of Philosophy and the Program on
Ethics and Public Affairs at the Mansfield Center,
University of Montana, Missoula, MT, USA

Holmes Rolston III is widely known as the “father of environmental ethics” for his relentless articulation of the presence of natural values in nature. He is also known for his work on the reconciliation of Christian theology and evolutionary biology during which he characterizes nature as “cruciform.” In 1997 he presented the

Gifford Lectures in Edinburgh, and in 2003 he was awarded the Templeton Prize in London. He retired as Distinguished University Professor of Philosophy from Colorado State University in 2008 (Preston 2009).

At the start of the 1970s, several environmental thinkers including Richard Routley and Arne Naess had begun to ask whether a new type of ethic for nature was needed, one that centered not on people but on the environment itself. Answering this call, Rolston published "Is there an Ecological Ethic?" in the leading philosophy journal *Ethics* in 1975. The publication of this article was thought by many to mark the birth of the field of environmental ethics. Rolston argued in this article that morality "is a derivative of the holistic character of the ecosystem" (Rolston 1975, p. 17). Ecosystems themselves held value that deserved our respect irrespective of their usefulness to humans. Over the next decade, Rolston cemented his place at the vanguard of those philosophers arguing for this "intrinsic value" of nature. For Rolston, intrinsic value existed objectively in nature, independent of any human value judgments. Other environmental philosophers, such as J. Baird Callicott, agreed that nature had value, but insisted this value could not exist objectively in nature, requiring instead a human judgment to actualize it. Rolston's position remained uncompromisingly objectivist about the existence of this value.

In Rolston's view, intrinsic value in organisms accumulated in the form of biological "achievements" that got "locked in" by the DNA of a species over time. Above and beyond individual organisms and species, the system itself was also a source of value, generating complexity and diversity through geological, hydrological, and evolutionary forces operating relentlessly through time. Value in nature was therefore not only instrumental, reflecting the usefulness of particular organisms and species to others; it was also intrinsic and systemic. These latter two types of value resided in the organisms that employed their selective advantages to secure their own goods and in the ecosystems that provided the supporting matrix in which those forces could operate.

A collection of essays titled *Philosophy Gone Wild* (Rolston 1986) was quickly followed by a systematic work *Environmental Ethics: Duties To and Values In the Natural World* (Rolston 1988). In these two books and dozens of articles that came after them, Rolston pressed his case for intrinsic and systemic natural value. Against those who argued all value is a derivative of human interests, Rolston countered that "systemic nature is valuable intrinsically as a projective system, with humans only one sort of its projects" (Rolston 1988, p. 198).

While this view on objective intrinsic value was his central position in environmental ethics, his work branched out into other areas of the new field including environmental aesthetics, environmental law, environmental economics, the ethics of wilderness preservation, and endangered species protection. In all of these areas, Rolston distinguished himself from many philosophers by the scientific rigor he brought to his arguments. In his position in environmental aesthetics (scientific cognitivism), for example, Rolston argued that "science becomes the primary avenue for perceiving landscapes, better than any other – necessary though not sufficient for their most adequate understanding" (Rolston 1995, p. 380). Rolston's prolific work ethic and devotion to the new field he helped create led to him becoming the founding president of the International Society for Environmental Ethics and the cofounding editor of the first journal in the field *Environmental Ethics*.

Rolston's work in environmental ethics had by necessity taken a largely secular form in order to satisfy his philosophical critics. But his idea of natural value accumulating in the biota over evolutionary time also had strong theological undercurrents. At the same time as he was publishing books and articles for philosophy audiences, he was also publishing for theological audiences. His 1987 book *Science and Religion: A Critical Survey* (Rolston 1987) sought to find room within the latest physical and biological sciences for a divine presence. In his version of evolutionary theism, Rolston insisted that, while evolutionary theory was the correct mechanism for explaining the changes in biological forms over time,

evolution by itself was not quite explanatory enough. “The universal principle (the best adapted survive) never entails any particulars (dinosaurs exist) not even when given the initial conditions (microbes, trilobites)” (Rolston 1987, p. 120). He suggested that there needed to be some other principle at work. Natural selection, he argued, is “only a fraction of some bigger truth” (Rolston 1987, p. 121).

As the debates about the anthropic principle and intelligent design unfolded around him, Rolston found his Calvinist background helping to inform his theological understanding of nature. The anthropic principle, which held that the universe had its initial conditions fine-tuned from the start by a divine being so that humans might eventually evolve, contained too much of the heavy determinism within double-predestination that he had rejected years earlier. Intelligent design, which insisted that a divine power was required to build certain complex biological structures that resisted evolutionary explanation, did not give adequate account of the contingency and chance pervading earth’s history. In *Genes, Genesis, and God* (Rolston 1999), a book based on his 1997 Gifford Lectures, Rolston found room for God in the evolutionary epic as the source of information, opening up the “possibility spaces” through which the mechanical processes of evolution operated. Rolston noted how biologists John Maynard Smith and Eörs Szathmáry had identified several key moments in evolutionary history when unlikely adaptations – such as the swim bladders in fish becoming the lungs that enabled them to survive on land – opened up vast new possibility spaces (Maynard Smith and Szathmáry 1995). Rolston suggested the presence of a divine power as the “ground of information” offering “the most adequate account of the origin of these information channels” (Rolston 1999, p. 359). The three moments of greatest historical significance – the start of the universe, the beginning of life, and the emergence of mind – are described in Rolston’s 2010 book *Three Big Bangs: Matter-Energy, Life, Mind* (Rolston 2010).

According to Rolston, the role of divine grace operating in the background of evolution finds its

parallel in human life. Individual persons, like individual organisms, suffer and die in the face of a harsh processes. God’s grace intervenes to ensure that there is benefit to all this suffering. Rolston’s theodicy worked the same way in both the human and the natural worlds. Environmental necessity was the mother of both cultural and biological invention. Nature is thus “cruciform” with Jesus, “not the exception to the natural order but a chief exemplification of it” (Rolston 1999, p. 307). Life is a passion play, well symbolized by the pasqueflower that emerges from snowbanks in the Colorado high country each spring. The discovery of the pasqueflower’s bloom at the end of a long winter leaves Rolston compelled by “the grace of life renewed in the midst of its perpetual perishing, generating diversity and complexity, repeatedly struggling through to something higher. . .” (Rolston 1999, p. 370).

Description

As the notion of “nature” is essential for the self-understanding of the European/Western civilization also theology has in its long history contributed to the development of the concept of nature. In the Abrahamic religions, “nature” is “creation” which exists out of its relation to God. God is regarded as the Creator of everything between heaven and earth, and classical Christian theology has interpreted God’s work as a making, preserving, and fulfilling of nature. The doctrine of creation offers the horizon for the whole understanding of Christian faith even if it historically often has been opposed to soteriology, the doctrine of salvation. A general challenge for Christian theology therefore is to relate God’s creation and God’s salvation to each other (cf. Conradie 2012). Are human beings as “images of God” placed above or among creatures? Is only man/woman or also nature in the need of liberation?

The view of nature and the use of it have undergone several changes in the history. In antique and medieval times, the notions of

“physis” and “natura” signified everything that existed, and the so-called natural theology, for example Thomas Aquinas, shaped the path for modern science by investigating Gods being through studying nature and by explaining the world from the image of God. The view of nature changes then radically in the nineteenth century. Humans and nature are distanced radically from each other and the human identity is not longer understood as a double belonging to divine-spiritual and natural-bodily spheres of reality.

In time with a progressing secularization and modernization, the change of the life-systems, for example in climate, reveals with an increasing clearness man as a rational and technical ruler over nature. Human codes of knowing about and acting in nature are out of balance with the codes of nature. Older natural theology does not any longer fit into this challenge and late modern theology is challenged to reconstruct the traditions of creation theology and to interpret in a new key the God who acts in, with and for a world threatened by his/her own image.

There is an indissoluble connection between one’s understanding of nature and God. A shift in the understanding of any one of these invariably causes the other to appear in a different light as well. Accordingly, any change in the modern understanding of nature simultaneously calls into question the understanding of God inhering within Christian life and Christian faith. From the 1970s, we can observe such a change in the image of nature and the image of God.

As “nature” turns into “the environment,” that is, nature affected radically by human social and technical activities, also beliefs in Creation and the Creator change. The emergence of environmental science and the worldviews and values of environmentalism in the increasing social movements catalyze this process even more. Theology has since then faced and responded in a manifold of modes to what we can call the environmental challenge. The emergence and rapid and dynamic development of the subdiscipline of ecotheology mirrors – in analogy to the connected subdiscipline of environmental ethics – this change of the interconnected concepts of nature and God. Are human beings the only ethical

subjects? Can one speak meaningfully about the intrinsic value and rights of nature? What are the pro et contra for anthropocentrism versus ecocentrism? Who and where is the Creator in the suffering of his/her creation? This change takes its course in the ethical challenge, but it is far from limited to this; rather, the ecological perspective expands to cultural, aesthetic, scientific, technical, political, and economical spheres. This complexity of environmentalism can also be observed in different approaches in ecotheology.

After Lynn White's famous blaming of Jewish and Christian faith as the "roots of our ecological crisis" in 1967, theologians have responded and revisited their biblical sources and traditions in the context of the environmental discourse. Even if White's historical description has been rejected by environmental historians, the deep interlinkage of religion and environmental practices and ideologies is at the core since then. While Protestant theologians have been in the forefront of academic ecotheology in the beginning, Orthodox theologians contributed with important perspectives on liturgy, aesthetics, and cosmology in the 1980s in the frame of ecumenical processes, mainly the "conciliar process for justice, peace and the integrity of creation" (JPIC). Catholic theology awakened late in the 1990s and has for example recently focused on sustainability as a central ethical principle.

Since the 1970s, churches and theologians have met the ecological challenge in three ways. Either one has regarded the environmental crisis just as reason to reformulate conventional doctrines of faith, or one has eclectically mixed up elements from ecological science and spirituality with selected elements from Christian tradition. A third way has sought for critical-constructive mediations of ecological insights and interpretations of God. This way, where theology works as a part of a larger ecological discourse as well as it asks for specific Christian reconstructions, represents the mainstream of creation theology in the second part of the twentieth century. The understanding of God itself is challenged by the suffering of nature caused by men and women who supposed to be images of God, the creator. Methodologically, one can differ two modes of doing

theology, one dogmatic in a direction from faith to environment (ecological doctrine of creation) and another contextual, departing from the state of nature and moving toward the reflection on God (theological ecology).

A pioneer of ecological theology in the USA was Joseph Sittler who already in 1961 clearly viewed the "new situation" confronting the proclamation of faith, which he encountered with his cosmic Christology. While process philosophy, for example John Cobb, offered an important background warrant for ecotheology in the USA, European theologians have met this with a far more skeptic attitude. German biologist and theologian Günter Altner was the first who since 1974 interpreted the environmental degradation in the light of a Christian theology of the Cross, where nature revealed a civilization at crisis (cf. Altner 1991). Several theologians related the conflict between humanity and nature to the conflicts between different classes, regions and people, and also to the gender conflict, and a wide-open perspective of liberation and reconciliation was brought into the heart of the ecumenical social ethics after 1970.

A first extensive and influential reinterpretation of Christianity was offered in 1985 by Jürgen Moltmann in his "ecological doctrine of the creation" (Moltmann 1985). Different themes from Christian tradition were loosely linked to new scientific insights and eco-ideology in order to work out the relevance of Christian faith for finding ways out of the contemporary crisis of society and nature. Disciples from different confessional traditions – as from, for example, Karl Barth's antinatural revelation theology or from neothomistic universalist Catholicism – tried to respond to the ecological challenge, even if one not always did succeed to find synthetic correlations with the fathers of tradition and the challenge of the new situation.

Ecofeminism reflects about the interconnection of gender and the environment and has created a significant impact on ecotheology. Catharina Halkes, Anne Primavesi (Primavesi 2000), Sallie McFague, Rosemary Radford Ruether (Ruether 1994), and Heather Eaton (Eaton and Lorentzen 2003) have from different

angles produced alternative visions of human encountering of nature.

After the widening of the academic ecotheological discourse from the first to the third and fourth world in the 1990s, the approach of an ecological theology of liberation emerged. Leonardo Boff revisited ecological themes in the continuity of Latin American liberation theology (Boff 1995), Yvonne Gebara combined feminist and ecological reflections about liberation, and Sigurd Bergmann developed a normative approach where soteriology and ontology are interpreted in the notion of the “Gods liberating movement in creation” in a constructive correlation with Eastern Early Church theology, especially its Trinitarian and pneumatological traditions (Bergmann 2005).

Ecotheology was from the beginning an ecumenical affair. Especially the Eastern-orthodox contributions to the new discourse on nature were developed in the institutions and conferences of the ecumenical movement, especially in the World Council of Churches (WCC) and the Conference of European Churches (CEC). It was due to the orthodox representatives at the WCC assembly 1983 and especially to the Syrian-orthodox theologian and church leader Paulos Mar Gregorios that the WCC programme on “Justice, Peace and the Integrity of Creation” (JPIC) was enriched with the environmental issue so that the main agenda for ecumenical social ethics since then could focus on peace, justice, and ecological problems as the most prioritized challenges for Christians. Orthodox theologians enriched the somehow limited perspectives of Protestant thinkers with themes like sacraments, liturgy, trinitarianism, and beauty. A breakthrough for ecumenical ecotheology in Europe adapted by the churches took place at the concilium in Basel in 1989. For the first time after the schism between Eastern and Western Europe, all churches met in one common conference, and they were even able to make a strong consensus on the need for a more just and ecological order of world economics. The heritage of this strong ecological commitment in the European churches is developed in the “European Christian Environmental Network” (ECEN).

The European Ecumenical Forum of Christian Women has a subgroup on Ecofeminism and Ecology.

Together with an academically vital and manifold reflection, the ecumenical movement consisting of both many independent Christian groups and networks and of institutionalized church bodies constitutes a strong and sustainable basis for the further development of ecological constructive and critical theology and praxis (cf. Hallman 1994, and Hessel and Ruether 2000). This development is not just only about ideology reconstruction but also about the reacting and renewal of Christian community-life and mission. Alternative church banking, forests and land owned and ecologically used by churches, green parish economy, Christian church aid for women preserving nature, sustainable livelihoods, urban greening, and treeplanting are just a few among lots of examples where ecotheology and ecopraxis are in an intermutual exchange.

In its early phase, ecotheology dealt with large-scale problems in connection to The Club of Rome’s survival issues. In a second phase, it related to the issues of sustainability with regard to the Brundlandt-programme even if the position of the churches developed a much more dynamic and constructive view of “our common future” than the weak consensus of the United Nations. While the nations agreed on limits and extrinsic values for the ongoing exploitation of nature, the churches defined sustainability with regard to the intrinsic value of creation and made the claim of a radical conversion. In a third phase, ecotheology investigates the interconnection of economy and ecology by focusing on the question for what functions as God in the ongoing globalization process. Through their committed involvement in ecological discourses and alliance-building churches, Christian groups and theologians have shown the relevance of Christian faith as a transformative countervailing power in opposition to the forces of destruction, such as for example in work around environmental racism and ecojustice in solidarity with the victims. The dignity of the question where and how God acts in the ecological destruction and reconstruction is increasing in accordance with

the increasing environmental problems. At present one observe a new phase where the consciousness about accelerating climate change produces new challenges to all faith communities. In general, one can claim that climatic change also changes the conditions for faith communities and belief systems and that religious processes therefore essentially contribute to sociocultural processes of mitigation and adaptation. The history of 40 years of environmental theology has prepared the Christian faith communities to respond to the need of creative climate adaptation and since 2005, one can observe an increasing interreligious communication about how different faith communities can cooperate with regard to the painful challenges of the future.

Four international societies and networks represent not only environmental theology but the broader field of the study of religion and the environment in the global academic landscape. Mary E. Tucker initiated in 1996 the Forum on Religion and Ecology in the USA, while Heather Eaton developed the analogous Forum in Canada. After 2003, the European Forum for the Study of Religion and the Environment was initiated and chaired by the undersigned and the International Society of the Study of Religion, Nature and Culture was initiated by Bron Taylor in the USA. Networks in Africa, Latin America, and Asia are developing.

Self-Identification

Science

Theology develops as a scholarly self-critical reflection about different expressions of Christian faith and their contexts and relations to other religions and worldviews. Research and teaching take place in the universities either at theological faculties or departments at faculties of social science or humanities. Theological institutions are either hosted by a church organization or part of the national universities. In some countries such as Germany, agreements between the state and the church regulate their relation. Theological schools educate students for services in the faith congregations, schools, media, and other

social institutions. Historically, medieval theology represents the cradle of modern science. Environmental theology is usually not taught as an isolated subject but included in the different subdisciplines of systematic theology, biblical theology, and sometimes church history.

Religion

Environmental theology explores belief systems with regard to God, nature, and the environment, but it does not presuppose an individual belief or confession. Many scholars and students although are committed to different belief traditions and seek for to apply insights from environmental theology in their religious practices and in the ideologies of their faith communities. Also the so-called public theology includes the environmental theme at its heart and scholars of environmental theology therefore strongly influence the public self-understanding of faith communities. Insofar as one might regard also the environmental movement as a belief system one can also state important points of contact between the scholar's academic activity and his/her political commitment, a fact that is true even for many life scientists.

Characteristics

Environmental theology is distinguished from the other disciplines of theology by its focus on the interaction of human beings with their environment, and it highlights especially the ethical implication of this interaction. Also the connection between feminist theology and ecotheology represents a distinctive subdiscipline.

The rather amorphous field of Christian ecotheology is currently characterized by a number of distinct discourses, each with its own interlocutors, guilds, and forms of rhetoric. These include at least the following:

- Multi-faith collaborative discourse on “religion and ecology,” for example, in the context of the Forum of Religion and Ecology where “religion” serves as an umbrella term for various distinct theologies and “earth” for the one world within which various human cultures and religions emerged.

- Ecumenical discourse on ecojustice with regard to the threats of economic injustices and inequalities and ecological destruction.
- Numerous contributions to applied ethics on environmental themes such as climate change, biodiversity, and animal ethics.
- Discourse on an ecological biblical hermeneutics, for example, in the context of the Earth Bible series.
- Reconstructive work on the ecological ambiguities and wisdom embedded in particular Christian traditions (e.g., the Franciscan tradition).
- Theological reflection on Christian beliefs and symbols (e.g., within the context of the Christian Faith and the Earth project).
- Theological reflection on liturgical renewal, for example, on the celebration of a “Season of Creation”.
- Reflections on a wide variety of Christian earthkeeping projects, missionary endeavors, and the greening of Christian institutions.

It is striking that such discourses remain somewhat disjointed from one another and that the methodological differences between the various theological subdisciplines remain unresolved in this context.

Relevance to Science and Religion

While the discourse about “science and religion” has prioritized “big science” as a dialogue partner – and neglected environmental science and also technology – and while it only to a limited degree has included reflections about the ethics of science and the power alliances of science with other social institutions, environmental theology is driven by the ethical problems that arise when science is applied to nature. Sometimes big science has been used to develop a theological vision that makes use of science to develop an ecological moral to the story of evolution. While classical natural science has been driven by anthropocentric interests to use nature for humanity’s sake, environmental science certainly contains methods and insights from science but applies these with a higher ethical

consciousness in alliances with political and economic institutions. Environmental theology is closely connected to the emergence and development of environmental science, and it contributes dynamically to the establishment of the “environmental humanities” which organize themselves at present in order to achieve a better balance of faculties in environmental science. The contributions from environmental theology to the discourse on science and religion are therefore not mainly interested in ontological or epistemological questions but formulate critical perspectives to the ethics of science and to its sociopolitical significance as either life-destructive or life-enhancing scholarly practice. Environmental theology contributes – by operating with a central idea of the intrinsic value of life and ecojustice – to the ongoing transformation of science as a human rational practice for the best of both man/woman and nature.

Sources of Authority

Environmental theology is still a young discipline in its dynamic development, where an increasing number of committed scholars on different continents are contributing to its rapid growth and scientific and public progress. Some important scholars have been mentioned above. Following the advancing institutional structuration of the field, one should mention Mary C. Grey, Celia Deane Drummond (Deane-Drummond 2008), and Sigurd Bergmann in Europe; Heather Eaton, Larry Rasmussen, John Cobb, and Dieter Hessel in North America; Denis Edwards and Norman Habel in Australia; and Ernst Conradie in South Africa (Conradie 2006). The World Council of Churches has furthermore offered a significant international arena to develop environmental theology. With regard to the broader field of the study of religion and the environment, one should also mention Mary E. Tucker and Bron Taylor in the USA who have established influential academic bodies. Both the European Forum for the Study of Religion and the Environment and the International Society for Religion, Nature and Culture arrange regular thematic events which

are published, and a couple of journals, such as “Worldviews,” are prioritizing reflections from environmental theology. The former journal “Ecotheology” has been taken over in 2007 by the International Journal for the Study of Religion, Nature and Culture.

Ethical Principles

The main ethical principles for all academic disciplines are of course valid also for environmental theology. Furthermore the respect for the intrinsic value of nature and life generates a self-critical perspective which runs through all investigations of the discipline. The concept of ecojustice/environmental justice, which expands the concept of justice from the human to the ecological sphere, is deeply and widely explored in the discourse of environmental ethics, and ecotheologians have contributed with significant perspectives about how such a concept is rooted in deeper cultural and religious beliefs. Other ethical concepts have been investigated such as feminist ethics, discourse ethics, and virtue ethics, and recently, climate ethics and animal ethics have been explored extensively by ecotheologians.

Key Values

The increase of human self-critical consciousness about his/her interactions with nature, where the human skills are interpreted in the light of faith in the triune Creator, a belief that relativizes all total power claims of humans as rulers over nature.

Conceptualization

Nature/World

Nature/world is perceived as creation. In its origin and development as well as in its perishability, it exists out of its relation to God.

Human Being

According to the biblical story, man/woman has been created as “the image of God.” The old

church has interpreted man/woman as a “microcosm” of the whole creation and a “mediator” between the Creator and all creatures. Environmental theology rejects that this implies a superiority of humans over other beings.

Life and Death

Life is not a commodity but a gift; life includes death as a natural component.

Reality

As all that exists is connected to God, also reality in its manifold is sacred.

Knowledge

According to the classical apophatic tradition, knowledge about God can never encompass the nature of God but only the God who acts. Only human experiences with God in nature can be studied. Ecotheologians use a broad range of scientific epistemological concepts from the humanities, social sciences, cultural studies, life sciences, and environmental science.

Truth

Truth appears as an approximation of insights into the interplay of religious belief systems and environmental practices and ideologies.

Perception

The perception of the environment is an essential human skill which underlies all thinking and acting in, with, and through nature. Environmental theology has in its beginning mainly dealt with cognitive and moral dimensions of the human-nature interplay but explores in its later history also the aesthetical dimension through studies of imaginations, artifacts, perceptions, and awareness.

Time

Time and space are central categories of the human conceptualization of nature and the environment. Environmental theologians have criticized reductionist understandings of time as crucial for anthropocentric and instrumentalist worldviews, and they emphasized the entanglement of different time modes in deep

understanding of sustainability. The significance of space has been accentuated by “theology in its spatial turn,” where environmental theologians have overcome Newtonian concepts with reflections about lived space which unites physical, social, and imagined space. Concepts of both time and space have been investigated in their embedment in religious beliefs.

Consciousness

Consciousness is a central term in psychology and neuroscience, which as such is not dealt with extensively in environmental theology.

Rationality/Reason

Concepts of reason and rationality belong to the central parts of the Western self-understanding through the ages. As environmental theology also includes the philosophy of religion, it investigates also how concepts of reason are transformed by ecological worldviews. Especially ecofeminist theologians have reflected about how images of gender and images of nature affect concepts of rationality, and how rationality not at all can be understood in an universalistic way but must be analyzed in its contextual (including natural and cultural) embeddings.

Mystery

The term “mystery” emerges in religious contexts, and is also frequently at work in different approaches of environmental theology. In the dialogue between science and religion, it can help to express common attitudes to nature which one can never fully but only partially analyze. Mystery further appears in combination with other terms such as wisdom, the Sacred, and sacraments.

Relevant Themes

The concept of “the Sacred” has been crucial in the invention of modern sociology as well as the history of religion. Environmental theology uses the notion to analyze what people regard as sacred and how these images relate to religion and faith traditions. Especially the sacredness of nature and earth seems to characterize

worldviews and values in late modernity. As ecological worldviews develop belief in the earth as one common animated space, also concepts of space are at core in environmental theology which investigates how images of nature, space, and the sacred interact.

[Theory of knowledge](#)

Definition

Epistemology is an academic discipline and area of inquiry within both philosophy and psychology. As a result, epistemology holds a vitally important place in the boundaries between the sciences and the humanities. Accordingly, epistemology is the central focal concern within the philosophy of science. Broadly defined, epistemology is the study of knowledge, including the nature of knowledge, the sources of knowledge, the structure of knowledge, and the limits to knowledge. On the side of philosophy, the emphasis has historically been on the limits of knowledge and how it might be distinguished from belief and opinion. On the side of psychology, the emphasis has been on the development of knowledge and cognitive

structures associated with knowledge. In modern times, the two approaches have both focused on what might be called naturalistic epistemology which further blurs the boundary between philosophy and science in the area of epistemology.

Discussion

Historically, philosophy attempted to draw distinctions between knowledge and belief, with knowledge associated with certainty and justification and belief associated with doubt and lack of justification. In the *Republic*, Plato (309 BCE, [estimated](#)) went so far as to associate knowledge with eternal, unchanging truths about immutable objects of knowledge (forms); Plato associated beliefs with the world of change, perception, and everyday experience. Much of Plato's epistemology did not survive classical times, but the association of knowledge with eternal truths and certainty persisted until the modern period. In Descartes' (1637) *Discourse on the Method*, there is the application of an early form of the scientific method to philosophical issues in an attempt to establish with certainty what can be known. Descartes' (1641) *Meditations on First Philosophy* carries his method of doubt further in an attempt that it can be established with certainty that the self is essentially a thinking being and that the existence of God can be demonstrated with certainty.

It is perhaps ironic that Descartes' (1637) method of doubt ultimately led to a fundamental shift in philosophical epistemological away from deduction a priori methods (logic aimed at establishing conclusions with certainty) to what can be called naturalistic epistemology, which is an approach to use scientific methods to examine the sources and structures of knowledge. In naturalistic epistemology, there is no longer a strong distinction between beliefs and knowledge. On the philosophical side of naturalistic epistemology, one will find ongoing attempts to map out the boundaries between sense and nonsense – a mainstream philosophical enterprise – based on findings in psychology. On the psychology side of epistemology, one will find scholars

addressing questions about (a) the sources of belief and knowledge (e.g., perception, habits, etc.), and (b) the structure of knowledge and belief networks (e.g., mental models, schema, etc.). Happily, there is a fair amount of interaction between philosophers and psychologists, which suggests that epistemology will remain a viable and important area of inquiry indefinitely.

Traditional epistemology approached these questions using deductive methods and with *a priori* notions of the nature of knowledge (e.g., knowledge involves certainty), the sources of knowledge (e.g., valid deductive arguments and perhaps direct and immediate perceptions), and structure of knowledge (e.g., knowledge structures are based on undeniable truths).

Naturalistic Epistemology

Naturalistic epistemology embraces a scientific approach when exploring questions about the theory and nature of knowledge (Spector 2012). For example, epistemologists investigating the nature of knowledge look at what people in fact accept as well founded and reliable rather than restrict knowledge to that which is absolutely certainty (e.g., mathematical knowledge). When investigating sources of knowledge, epistemologists are likely to examine what people actually use and report using as sources rather than be constrained to deductive argumentation. When considering the structure of knowledge, epistemologists are likely to consider groups of beliefs and their interconnections rather than focusing on a few undeniable axioms of truth (Quine 1992; Quine and Ullian 1978).

In naturalistic epistemology, there is primary emphasis on knowledge development and the formation of beliefs (Kornblith 1994; Spector 2012). Knowledge is now viewed as something that can and does change, both within the individual knowing subject and within a community of believers. Knowledge is no longer about fixed object. However, beliefs that comprise a body of knowledge are still viewed and critiqued as more or less well justified, and the interrelationships and interdependencies among a set of beliefs

become a critical aspect of a belief or knowledge network.

In naturalistic epistemology, the process of coming to know receives as much or perhaps more attention than discrete bits of knowledge that might result from learning and experience. In educational research that draws on epistemology, this is evident in the emphasis now placed on collaboration, interactions with peers, motivation, and self-regulation. Naturalistic epistemology humanizes knowledge, which is no longer viewed as something possessed by an elite group of scholars. Everyone comes to know and believe a variety of things. Not all beliefs are equally well justified or equally acceptable, but everyone has beliefs, and how they are developed and how they change is of interest to naturalistic epistemologists. Naturalistic epistemology provides a basis for the examination and evaluation of controversial beliefs: (a) Does a particular knowledge claim fit well with other beliefs previously accepted claims? (b) Can the person making the claim produce and/or reproduce evidence in support of the claim? (d) Is there a reasonable cognitive basis for accepting a particular claim made by a person?

Historically, the success of the scientific method roughly coincided with a shift in emphasis within philosophy from metaphysics (what kinds of things exist?) to epistemology (what kinds of things can we know?). A subsequent shift from deductive to naturalistic epistemology occurred as more was being learned about human cognitive and noncognitive processes (Kim & Pekrun, in press). While philosophy was reacting to changes in the role and prominence of science and in particular psychology, there has been a resulting influence of naturalistic epistemology on science and psychology. Kuhn (1996) basically argues that epistemology (the philosophy of science) grounds all science. More recently, the concept of a web of belief (Quine and Ullian 1978) is a key concern with many cognitive scientists and learning researchers investigating how individuals and groups form beliefs and how those beliefs change over time and through experience. Quine & Ullian's view is that beliefs change as a whole – it is an individual's entire belief network that one

brings to an experience rather than a single belief. This constructivist perspective is even evident in Wittgenstein's (1922) *Tractatus* when he remarks that the world of the happy man is not the same as that of the unhappy man and that our beliefs wax and wane as a whole.

There are two critical foundations for naturalistic epistemological. First, there is the widely held view that people construct internal representations to make sense of new experiences and unusual phenomena. Understanding how these internal representations form and shape beliefs and knowledge is a core area of investigation in epistemology; this also happens to be a key concern for learning psychologists and educational researchers. As Wittgenstein (1922) stated, we picture facts to ourselves – we create internal representations in response to and in order to make sense of our experiences; cognitive psychologists call these internal representations mental models, schema, and scripts. The second important foundation concerns language. Not only do we create internal representations that no one ever directly observes in order to make sense of an experience, we talk about these representations (and many others things as well). There are what Wittgenstein (1953) would call language games associated with the discussion of mental models, schema, and other hidden internal mental states. These two foundations will be recognized as the foundation of social constructivism by many, which further emphasize the notion that philosophy does shape and influence both the natural and social sciences as Kuhn (1996) and many others have argued.

Important and Open Questions

There are alternative perspectives about epistemology and many open questions. Alternative perspectives include: (a) philosophical epistemology should be distinguished from psychological epistemology and remained focused on the philosophical questions concerning the nature of truth and certainty; and (b) philosophical epistemology should focus on the philosophy of science and continue to help differentiate scientific

inquiry from other domains (such as religion, politics, and esthetics). There are probably other legitimate perspectives as well. It is likely that a humanistic epistemological perspective can be elaborated that helps everyone develop critical reasoning skills and serves to frame discussions about important social issues (e.g., distinguishing creationism from evolution, framing the abortion debate, reconciling individual responsibility and national policy).

The fundamental thread underlying a naturalistic approach to epistemology is that the focus should be on how people in fact form and change their beliefs, how belief networks evolve, and what cognitive, noncognitive, and social factors influence beliefs and knowledge development. Within epistemology broadly considered, there are a number of open questions. For example, there is an ongoing debate with regard to the sources of knowledge – the internalism/externalism debate. The basic question in this controversy is whether a chain of beliefs must be grounded on or linked in some to an internal mental state or an external state of affairs (or both) in order to be considered well justified. While some epistemologists come down on one side or the other, it should be noted that many naturalists do not take sides; rather, they change the question into something more pragmatic, such as what is required for a particular belief or set of beliefs to be considered reliable and useful to a community of practice?

A second area of investigation in epistemology concerns the nature and status of *a priori* beliefs. Are there beliefs that can be considered well justified that are not related in some way to human experience? Those who might be called pure empiricists would insist on the notion that all belief and knowledge are based on and proceed from experience. However, when one examines how people actually come to form beliefs and expectations, many naturalists have noticed that *a priori* beliefs apparently can and do play a role in expanding what one (or a community) knows or relating what one has learned to something else one believes (Goldman 1986).

A third area of investigation in epistemology concerns the problem of induction which is

regarded as the fundamental way in which we learn about the world. While deductive methods, when correctly applied, result in certainty, inductive methods, when correctly applied, result in more or less probability. One way to characterize the problem is to ask what underlies the inductive method. For example, suppose the induction is of this form: 90% of the randomly examined cases of X have involved Y; so, we can expect that about 9 out of 10 new cases of X will also involve Y. There is an unstated assumption – namely that the sample was sufficiently large and representative; this is worth determining before accepting the claim. In addition, there is a hidden premise – namely, the future (at least with regard to X's and Y's) will remain the same or resemble the past in relevant ways. But where is the evidence to support this unstated premise? Indeed, because it is a claim about the future, the evidence does not exist. One naturalistic way around this dilemma is to simply argue that humans do in fact apply or accept this unstated premise and have been doing so for a long time; perhaps it is even our nature to apply some kind of basic probabilistic sense about the association of events; perhaps, there is an evolutionary advantage to holding the view that the future will resemble the past. Is this a claim that can be empirically investigated? The answer is not all that clear.

Epistemology as practiced in the twenty-first century emphasizes how people come to believe and form their beliefs. The concept of a learning community associated with social constructivism is widely accepted among most epistemologists. The notion of language games and communities of discourse and practice are closely associated with modern naturalistic epistemology and the emphasis on practical norms and reliability of beliefs (Wittgenstein 1953).

Epistemology, Evolutionary

Neil Spurway

University of Glasgow, Glasgow, Scotland, UK

Description

If we accept that, at the level of immediate causes, human beings are as totally the products of ► [evolution](#) as any other living forms, many traditional philosophical questions must be radically reconsidered. The assessment of the nature of human knowledge is a major case in point. Evolutionary ► [epistemology](#) (EE) is the working out of such an assessment, starting on the basis that

not only our bodies in all their features – including sensory and nervous systems – but also mental functions are wholly the products of ► [natural selection](#) on the surface of this earth.

The Biological Aspect

The evolutionary viewpoint provides a perspective on the limitations of our sensory and mental capacities and yet, simultaneously, an assurance that the judgments we make about the material world are reasonably reliable. Considering sensory functions first, our eyes can detect only a narrow range of the electromagnetic spectrum, yet it is a range to which most material objects which we might wish either to avoid or grasp are opaque, so we can see them by utilizing this waveband. Also, our brightness sensitivity self-adjusts over a range of about 10^8 , and when maximally dark-adapted, our vision reaches the ultimate physical limit, one photon being sufficient to excite a rod. For hearing, there is no similarly absolute physical limit, but we can hear sounds sufficient to vibrate our eardrums just 1/10th the diameter of a hydrogen atom – yet only in a frequency range safely above those of body noises, which otherwise would deafen us. On the other hand, predatory birds which hunt from many metres above the ground have higher visual acuity, many animals can hear higher frequencies, our touch and smell capacities fall far short of those in species to which one or other of these sensory modes matters more, and we have no capacity to detect electrical signals as some fish do, the polarization of light like some insects, etc. Electrical signals are the sequence of electrical impulses generated and transmitted by neuronal populations, which as a whole, at systemic level, are considered synonyms of EEG and/or EPs. What determines the capacities each species has? The inescapable constraint is, of course, physical feasibility: an X-ray eye will never be more than a fictional concept. Within what is physically possible, however, the determining influence has been the evolutionary cost/benefit ratio. “We have developed ‘organs’ only for those aspects of reality for which, in the interests of survival, it was imperative for our species to take account” (Lorenz 1977).

Similar arguments apply to brains. Much of the detail is highly technical, but some points are easily understood. For instance, in human beings, the areas of the ► [sensory cortex](#) devoted to thumb and finger tips, and to lips, are much larger than those to limbs and trunk – the relevant factor being the importance of tactile discrimination in the respective body parts, not their own surface area. Nor should it be assumed that the mechanisms determining innervation density are entirely genetic. A fetus at about three-quarter term has far more nerve ► [synapses](#), sensory and motor, than it will have a year or two later: extensive ► [perinatal](#) elimination of less useful synapses occurs in parallel with reinforcement of others (Edelman 1987). Such selective shaping of the nervous system by the environment is accomplished very rapidly compared with the geological timescale of the genome’s evolution. “The Darwinism of synapses replaces the Darwinism of genes” (J-P Changeux) and occurs much faster. However, whichever the mechanism of selection, we may conclude that, within the limits of feasibility, both the information captured and the data-processing capacity applied to it are biologically determined by their cost/benefit ratio. Looking back to the previous quotation from Lorenz, not just our physical but our mental “organs” – our capacities to undertake particular forms of thought and formulate particular kinds of concept – have been selected by their contributions to our ancestors’ survival and reproduction.

The fundamental driving force behind this fact was put “crudely but graphically” by Simpson (1963): “The monkey who did not have a realistic perception of the tree branch he jumped for was soon a dead monkey – and therefore did not become one of our ancestors.” It is no longer thought that monkeys, *sensu strictu*, are direct evolutionary precursors of human beings, but Simpson’s comment can be read with no loss of impact in terms of the common precursor of *Homo sapiens* and modern monkeys. Furthermore, what is true of spatial and other physical judgments must, from a Darwinian standpoint, be true of biological and social judgments also. The consequences of being wrong would in many cases have been fatal, and in all others, they

would have been failure to thrive in the competitive world. But we *have* survived, and emerged from a network of ancestors who all survived, so our social dispositions have, over the course of history, been on balance valuable, and our objective concepts highly trustworthy. Of course, we are not born with detailed knowledge of our individual environments, let alone anticipation of the uncountable number of events which will occur in a given life. What is conveyed in our DNA, and more finely tuned by synaptic competition, is responsiveness to particular forms of regularity in our environments – initially, in the evolution of the species, the physical environment; later, increasingly the social one. An example of the first kind is that nervous systems are not predisposed to judge the leap to a particular branch but to make spatial judgments generally. An instance of the second kind is that the brains of human infants are not adapted to the learning of German in one child and Chinese in another but in each to the learning of *language* generally. However, the extraordinary speed with which we do learn the language(s) heard all around us in our early years must give the strongest indication to any doubter that the propensity for such learning is, indeed, inborn.

The Philosophical Aspect: Part 1: Fundamentals

Simpson continued from his comment on the tree-dwelling monkey: “Our perceptions do give true, though not complete, representations of the outer world because that was and is biologically necessary, built into us by natural selection. If it were not so, we would not be here!” By the same token, we may add that not only *perception* but also many aspects of *conception* must be reasonably accurate. Competition searchingly tests those concepts which have direct survival consequences, though not those for which this is not the case. Some of the latter category will be considered under heading “[Relevant Themes](#).” The former inextricably embody and imply the reality of the world perceived – we may know that world imperfectly, but we know it adequately for our survival. EE therefore gives us justification for cautious confidence in the approximate validity

of our concepts of the world: it makes sense of common sense! Proponents of EE contend that no other philosophical stance justifies such confidence.

Readers with any knowledge of the history of philosophy will by this point have perceived that EE represents a distinctive position in relation to the debate, extending from Plato to the present, about the existence or otherwise of innate ideas. Empiricists, of whom probably the most extreme was Locke, have always denied that we have such ideas – the mind of a newborn baby is, to them, “*tabula rasa*,” a clean slate. The opposite school, broadly classed as Idealists, has maintained that we perceive the world in terms of ideal concepts with which we are born. The earliest fully recorded version of this stance is that of Plato. But Darwin himself commented in his notebooks: “Plato says in *Phaedo*, that our imaginary ideas arise from the pre-existence of the soul, are not derivable from experience. Read monkeys for pre-existence!” Before this, he had already said, “He who understands baboon would do more towards metaphysics than Locke.”

An account of innate ideas more acceptable to the relatively modern mind was that of Kant. For him, concepts such as of space and time (concepts fundamental to Newtonian physics) are possessed by us *a priori*: they are not products of our personal experience but instead are the basics in terms of which we interpret all experience. Yet this has the unhappy consequence that, as we can never assess the world without these *a priori* concepts, we can never know if they are right. Nor can Kant’s approach explain how such concepts arose. William James, at the turn of the twentieth century, and more recently and consistently Konrad Lorenz, argued that they are not mysterious but products of natural selection – and consequently trustworthy: if not perfectly correct, they are pretty sound: “In the early years of the Second World War, when by coincidence he was a professor in Königsberg [Kant’s home city], Konrad Lorenz used Darwin’s idea about the formative role of the past to put the finishing touches to Kant. He argued that Kant’s scepticism about what the world is really like was unjustified because the cognitive structure

which enables us to know what the world is like had evolved through natural selection. The reason why our minds have this particular, and no other, cognitive structure ... must be that we have evolved and not flown in, so to speak, from outer space. Our cognitive structure has been selected by and, therefore, reflects or represents, the real world" (Munz 1993).

So what is inborn in the individual has arisen by the accumulated actions of natural selection upon countless generations of ancestors. In technical biophilosophical language, such inborn propensities to form concepts are "ontogenetically *a priori*, but phylogenetically ► *a posteriori*" (Lorenz 1977). Thus, "The great resistance of the empiricists to innate knowledge is made irrelevant ... in the form of a more encompassing empiricism" (Campbell 1974). To take an even broader view: "From the perspective of biology, knowledge ... is a form of self-reference.... The knower is part of the known, and has been shaped by what is known. The reflector reflects, more or less adequately, because it is itself part of what is being reflected. The biological perspective, therefore, provides an assurance that the reflector is adequate and also explains at the same time how it has been shaped by natural selection to be adequate" (Munz 1993). Again: "... the impressive order in nature is not, as has been claimed by idealistic philosophy, a product of our thinking and imagination., on the contrary, human thought itself is a product of the emerging order in nature" (Wuketis 1984).

One more instance is the inveterate human disposition toward generalization and induction. Hume pointed out that induction can be justified only psychologically, not logically, but EE explains why we all have this psychological drive: living beings can only adapt to consistent features of the world, but it is imperative for their survival that they *do* so adapt: conscious beings must therefore have the propensity to look for such consistencies.

The Philosophical Aspect – Part 2: Exploratory Knowledge

If human understanding were limited to that which could be directly derived through innate

concept-forming propensities, its rate of progress would be restricted to that at which DNA could mutate – either the DNA which directly affects these propensities or that which modifies rates of synapse change. Individuals could learn from experience, but there is no evident *physical* mechanism by which their learning could be passed on faster than the mutation rate. (The assumption that it could be conveyed by inheritance would be an instance of Lamarck's mistake.) Yet the most superficial glance at the human world shows that individuals can transmit their learning at rates many orders of magnitude faster than that of mutation. The processes involved are, of course, sociocultural, not mechanistically biological.

Mainstream evolutionary epistemologists, such as Lorenz, Campbell, and Vollmer, regarded each actual concept we form on the basis of our inherited propensities as a hypothesis about the world: "hypothetical realism" is the label given to the resultant epistemological stance. These "hypotheses" are, of course, challenged by our encounter with our surroundings, and where they prove unfruitful, either *we* shall be eliminated (if they have drastic short-term consequences) or *we*, as conscious beings, will eliminate *them* in favor of alternative hypotheses which will in turn be put to experiential test.

An even more eminent philosopher, Popper, although only fully espousing Darwinism quite late in his intellectual life and never using the term "hypothetical realism," took what was effectively this idea forward to form the basis of his mature philosophy of sophisticated knowledge and particularly of science. Although asserting the consistency of knowledge growth "from the amoeba to Einstein" and regularly referring to his viewpoint by the label "EE," Popper (e.g., 1972) had little concern with the biological history, or the mechanisms, of *natural* selection. His chief interest remained, as it had always been, the process of successive "conjectures and refutations" by which knowledge advances in human societies. This is an aspect of the contention, sustained throughout his writing, that hypotheses can never be proved but should instead be so stated that they make

specific predictions vulnerable to challenge; their success, if these predictions are not refuted, is merely that they have for the time being evaded disproof. This is analogous to natural selection, but the mechanism is different. Of the other authors cited, only Campbell *passim* and Munz, in much of his writing, have had in mind this conscious level of conjecture and potential refutation when they used the term “EE.” From Darwin, through James and Lorenz to Vollmer (1984) (other authors cited by Campbell 1974) the earlier, biological processes, affecting the unconscious propensity to form basic concepts and the selection of the better ones by preferential survival, not the highly conscious formulation and frequently rapid, purely mental rejection of sophisticated ones, is what “EE” refers to. Each is a valid meaning, but they should not be confused. Bradie (e.g., 2004) has distinguished them by the labels “EEM” and “EET,” respectively.

Nonetheless a final, but highly important, point must be that in neither mode of learning is a model of the external world considered to be imposed on the living entity by that world. Unicellular and other simple organisms do not even have body systems which could learn this way, yet by natural selection, they become increasingly adapted to the world over evolutionary time and so may be regarded as having acquired information about it. They have done so by “random mutation and selective retention” (Campbell). This of course is not epistemology, but the learning processes which are within the province of epistemology are considered to be contiguous with such primitive learning. Animals with nervous systems, to which the concept of an epistemology begins to become applicable, might more reasonably be thought to acquire information receptively by the action of the outside world upon the individual. However, it is argued that such a concept tacitly pictures the world as consisting of discrete bits of information, which could be picked up by passive response or painstaking observation. Yet the world “is not labeled” (Edelman), and the radical evolutionary epistemologist contends that such passive information acquisition never happens. Instead, the “labeling” is done by the organism, imposing its

comprehension patterns on the world which it experiences. Random “conjecture” and the risk of refutation are thus the picture of all learning in EE – slowly, through the evolutionary elimination of less appropriate “conjectures,” among organisms without conscious thought (EEM), and much more rapidly, within the individual, where the effectiveness of a conjecture can be consciously assessed (EET).

Justified and Practically-Effective Belief

The core of mainstream epistemology is a search for the characteristics of justified, true belief. It has therefore, as Bradie (2004) stresses, been less concerned to describe the processes of knowledge acquisition and concept formation than to prescribe how these activities should be undertaken for their outcome to be trusted. EE is equally concerned with justification but looks to the fact of concept survival to provide it rather than to the method by which the concepts were arrived at. And it regards the beliefs so justified, not as ever being certainly true but as being “well-formed and reliable hypotheses” (Tomas Hançil) – reliable, that is, in making our practical way in the world. Thus, EE (with emphasis on EEM) offers strong grounds, independent of traditional philosophical speculations, for believing that the world we sense is objectively real, that our fundamental concepts of it approximate usefully to that reality, and that we can gradually extend those concepts in the direction of yet better understanding by formulating our conjectures tightly enough that they can be subject to experiential test – ideally, by direct experiment (EET).

Among philosophers who are in the mainstream yet sympathetic to the evolutionary approach, the most common challenge is to the radical version of EET upheld by Popper and Campbell. This challenge concerns their contention (designated “Thesis Darwinism” by Nicolas Rescher) that human hypothesis generation is initially completely random, albeit that a large percentage of our hypotheses are rejected as soon as we are aware of them. Such a claim may soon become susceptible to empirical test by the developing techniques of cognitive

psychology. Meanwhile, Michael Ruse characterizes it as a “disanalogy” between biological variation (which seems truly random) and hypothesis formation. Philosophical critics such as Rescher and Ruse argue, and almost all practicing intellectuals, scientific, and otherwise would agree, that only hypotheses which appear to have some prospect of success are ever formulated, though the subsequent selection processes are as radically refutational and Darwinian as Lorenz, Vollmer, and all other evolutionary epistemologists have steadfastly maintained.

Self-identification

EE is a philosophical position based upon science.

Characteristics

EE offers the only understanding of human knowledge which takes its origin from the standpoint that human beings are products of evolution by natural selection.

Relevance to Science and Religion

EE is clearly compatible with simplistically naturalistic thought and thus with an atheistic view of the world. However, if one holds a concept of different levels of causation, operating in parallel upon the same observed phenomena, such a conclusion need not follow. Sympathetic exploration of the implications of EE for the science-religion dialogue is nevertheless in its infancy. Stanesby (1985) treated the subject broadly, suggesting that Popperian “conjecture and refutation” (EET) was appropriate as an account of theological as well as of scientific thinking – though, perhaps inevitably, it is less clear what would constitute the refutation of a theological conjecture, not concerned with this world, than a scientific one. By contrast, Burhoe (1972), and more recently Tomas Hançil, contended that human beings have access to nonphysical information, and the resulting concepts are as subject to

evolutionary challenge as physical ones. Yet this surely departs from the principles of EE? Nevertheless, Van Huyssteen (2006) urged that “... for theologians the following should be true: if we take the theory of evolution seriously, we should take evolutionary epistemology seriously,” and “... it would be a serious mistake to think that ... one could conceive of an epistemology independently of biology.” In turn, Spurway (2009), while endorsing these sentiments, questions whether van Huyssteen has in fact followed through the theological implications of EE radically enough. He argues that the more metaphysical and other worldly theological contentions have never been, and can never be, subject to the reality checks which justify our trust in the utility of physical world concepts, and so must be viewed with the greatest caution and restraint. See also section “[Relevant Themes](#)”.

Sources of Authority

The primary authority of EE is rational argument; support from individuals must, by its nature, be of secondary account. Nevertheless, the fact that Darwin himself was clearly thinking along such lines (as indicated by the two notebook quotations in section “[The Philosophical Aspect: Part 1: Fundamentals](#)”) encourages those inclined toward such a position. The subsequent commitments of such great figures as James (psychology), Lorenz (ethology), and Popper (philosophy) reinforces this.

Ethical Principles

The ethical principle guiding EE is fearlessness in the search for truth.

Key Values

The key value of this discipline is that evolution by natural selection should be recognized as the paramount influence determining human sensory, cognitive, and rational capacities.

Conceptualization

Nature/World

For EE, nature has been the crucial influence on the emergence of cognition, until supplanted very recently (on the evolutionary timescale) by organized society.

Human Being

It is of the essence of EE that human being is a state inextricably and totally integrated with that of all other organic life.

Life and Death

Life is conceptualized within EE as wholly a product of natural selection, operating on random changes originating at the molecular genetic level.

Reality

Reality for EE is all that of which we are a part, with which we can in principle interact directly or indirectly, and which we can know by observation or deduction.

Knowledge

Knowledge, though never perfect, always has some degree of adequacy as a contribution to survival. It takes two forms: implicit knowledge of (some region of) the world, embodied in the physical structures of every living form, and explicit knowledge, held in the minds of advanced animals and humans. Both forms are considered to be the consequences of variation and selective retention. The physical variation (EEM) is always random, but whether the conceptual variation (EET) is equally random is contested.

Truth

Truth, for EE, is that totality of facts about the world to which we increasingly approximate as our knowledge advances.

Perception

Perception is the formation of a sensory image of some aspect of the world in a conscious mind.

Time

The real passage of time is a concept fundamental to evolution and therefore to EE.

Consciousness

EE conceives consciousness as that property of a complex brain which, inter alia, enables the individual to advance his/her understanding by making repeated conjectures and, in comparing their predictions with experience, subjecting them to potential refutation.

Rationality/Reason

Rationality, for EE, is that process of analysis of concepts and their implications which, though in itself abstract, brings to bear a set of criteria honed by natural selection, over the period of evolution during which consciousness has existed, to tally with experience of the world.

Mystery

EE has no specific concept of mystery but seeks to explain many aspects of human cognition which would otherwise be mysterious, such as the universal disposition toward induction and why many of our practical concepts fit the world so well, by the operation of natural selection.

Relevant Themes

It is of the essence of scientific method to subject explanatory conjectures about the world to potential refutation by checking their specific predictions (predictions which they make but rival explanations do not) against experimental or other observation (Popper 1972 *et prec.*). Religious conjectures which are also about the world (sooth sayings, prophecies) are in principle open to similar tests and, where they differ from scientific predictions on the same topic, are therefore liable to result in conflict. The same may sometimes be true of explanatory retrodictions, such as those of creationism and intelligent design – areas in which the conflict is currently active and intense. By contrast, religious conjectures about events and affairs not in this world – whether in a hypothesized “other world” or

“before/after” physical time – should have no interface with science, and thus, no basis for conflict with it.

Those comments are not specific to EE. It has, however, recently been argued that religious concepts themselves – not their predictions but their claimed truth content – are vulnerable to critique from the standpoint of EE (Spurway 2009). This is because what is subject to natural selection is behavior. Concepts of the physical world lead to behaviors which will only be advantageous if the concepts are highly accurate – if the monkey’s space concepts are not correct to within a very small percent, it will miss the branch. From the standpoint of EE, it is precisely for this reason that we can place very considerable trust in the validity of such concepts. By contrast, the behaviors promoted by religions – social bonding, mating practices, self-sacrifice for the good of the group, etc. – depend on the strength of the belief which promotes them but not on its truth (e.g., Munz 1993). Thus, the survival of such beliefs provides no grounds for trusting their validity, and since there are an infinite number of ways of being wrong but only one of being exactly right (and probably only a very limited number of ways of being nearly right), the basis for any such trust is tenuous in the extreme.

[Christian epistemology](#); [Protestant epistemology](#); [Rationality of theistic belief](#); [Religious epistemology](#)

Reformed epistemology – one of the most widely discussed issues in contemporary Anglo-American philosophy of religion – was promulgated in the early 1980s primarily by the analytic philosophers and reformed Christians Alvin Plantinga and Nicholas Wolterstorff, whose pioneering papers on this topic were published in the anthology *Faith and Rationality* (1983). Reformed epistemology was developed mainly as a response to the so-called evidentialist

challenge to theistic belief, urged, for example, by W.K. Clifford and Bertrand Russell, according to which theistic beliefs such as “God exists” cannot be rationally held without successful proofs or arguments for the existence of God. Reformed epistemologists respond to this challenge not by seeking to show that there are successful arguments for the existence of God, although there may very well be such arguments, but by rejecting the evidentialist challenge.

A first reason that reformed epistemologists give for rejecting the evidentialist challenge is that it is poorly motivated. Many have motivated the evidentialist challenge by appeal to some form of classical foundationalism, according to which beliefs are rationally held only if they are more or less undeniable or can be derived from beliefs that are more or less undeniable. Beliefs that are more or less undeniable have often been taken to be of three basic sorts: self-evident beliefs, for example, the belief that “ $2 + 2 = 4$ ”; incorrigible beliefs, for example, “I seem to see something green”; and beliefs concerned with what is directly evident to the senses, for example, the belief that “there is a tree in front of you” when there is a tree in front of you. Reformed epistemologists reject classical foundationalism for two reasons: first, because it is self-referentially incoherent since the position is itself neither self-evident, incorrigible, or concerned with what is directly evident to the senses, nor is it entailed by beliefs that are, and hence does not satisfy its own criterion; and second, because it entails that numerous beliefs that are obviously rational are irrational, for example, the beliefs that “the world has existed for more than five minutes,” “there are other minds,” and “I ate cornflakes for breakfast” (supposing I ate cornflakes for breakfast), none of which are self-evident, incorrigible, or concerned with what is directly evident to the senses nor derivable from beliefs that are. Whether there are grounds for the evidentialist challenge other than classical foundationalism remains to be seen, but until they are put forth, the evidentialist challenge remains little more than a promissory note (Plantinga 1983, 62).

A second reason that reformed epistemologists urge for rejecting the evidentialist challenge, which brings us to the heart of reformed epistemology, consists in the claim that certain theistic beliefs can, for certain people in certain circumstances, be properly basic. A “properly basic” belief is here understood as a belief that belongs to that class of a person’s beliefs that the person is *prima facie* rationally entitled to hold noninferentially and on account of their immediateness and obviousness. The “circumstances” spoken of are given primarily by way of example; examples include people who upon having acted wrongly feel guilty in God’s sight, or who when life is sweet feel a sense of gratitude to God, or who have a sort of background awareness of the constant presence of God, and so on (see, e.g., Plantinga 1983, 80–81; Alston 1983, 108). People in circumstances like these will naturally form beliefs such as “God disapproves of what I have done,” “God is to be thanked,” or “there is a God.” According to reformed epistemologists, people who in these circumstances form these beliefs are *prima facie* rationally entitled to hold them. The term “*prima facie*” is important and indicates that the rational entitlement to hold the beliefs at hand is open to defeaters should the process by which the beliefs have been formed be shown to be defective. The general epistemological principle underlying this position is called “the innocent-until-proved-guilty principle” and is formulated by Wolterstorff as follows: “A person is rationally justified in believing a certain proposition which he does believe unless he has adequate reason to cease from believing it” (Wolterstorff 1983, 163).

There are various misunderstandings of reformed epistemology in the literature. One misunderstanding has it that reformed epistemology affirms the rational entitlement to take God’s existence as properly basic without regard to specific circumstances. This is incorrect; reformed epistemology affirms the rational entitlement to hold theistic beliefs as properly basic only given certain circumstances (e.g., Wolterstorff 1983, 155; Plantinga 1983,

78–82; Alston 1983, 103–105). Another misunderstanding has it that reformed epistemology, in affirming the rational entitlement to take theistic beliefs as properly basic, is taking them to be objects of knowledge (e.g., Zagzebski 1993, 199–208). This is incorrect; when reformed epistemology speaks of beliefs as “justified,” it means not that quality which distinguishes knowledge from true belief but rather rational entitlement in the sense of being within one’s epistemic rights or violating no epistemic duties. Plantinga has written much about theistic beliefs as objects of knowledge also, most importantly in his *Warranted Christian Belief* (2000), but these more recent writings do not redefine reformed epistemology but represent instead explorations of further topics. A third misunderstanding, which probably also results from confounding Plantinga’s earlier with his more recent work, has it that reformed epistemology presupposes the theological doctrine of a *sensus divinitatis*, that is, a cognitive faculty supposedly inherent in human beings by virtue of which human beings can sense God. This doctrine may be added to reformed epistemology as an explanation of how certain theistic beliefs are prompted in certain circumstances and has been so added, for example, by Plantinga, but reformed epistemology as such does not presuppose the truth of such explanations. The underlying epistemic principle of reformed epistemology is instead the above-mentioned innocent-until-proved-guilty principle; the *sensus divinitatis* doctrine is an optional addition to the central claims of reformed epistemology.

Among objections to reformed epistemology, the so-called Great Pumpkin objection is probably the most famous one. According to this objection, the epistemological principles that reformed epistemology draws on could just as well be used to say that people are rationally entitled to believe in all sorts of bizarre entities, say the Great Pumpkin. The claim is that if people are rationally entitled to believe in a supernatural entity such as God, then they ought also to be rationally entitled to believe in supernatural

entities other than God. A problem with this objection, however, is that it overlooks that reformed epistemology’s claim is that it is in specific circumstances that it can be rational to hold theistic beliefs, not that it is rational to hold such beliefs without regard to circumstances. A prerequisite for rational theistic belief is the existence of specific circumstances that call forth theistic belief in a person as something immediate and obvious. Thus, if belief in the Great Pumpkin’s existence is to be as rational as theistic belief, it must be prompted by analogous circumstances and present itself to the prospecting believer as something immediate and obvious. It is far from obvious that such circumstances obtain, however, for people do not spontaneously form beliefs about the Great Pumpkin. A similar objection, which Plantinga calls the son of Great Pumpkin objection, says that the epistemological principles of reformed epistemology entail a radical relativism in which various suspicious communities – the voodoo community, say – could legitimately claim that their distinctive beliefs are properly basic relative to their community and hence can be rationally believed by members of that community. A problem with this objection, however, is that it once again overlooks that it, according to reformed epistemology, only is in specific circumstances that people can be rationally entitled to hold theistic beliefs. So reformed epistemology does not as such entail that voodoo practitioners can legitimately claim that their distinctive beliefs are properly basic; it would only entail this if it were committed to holding that there are justification-conferring circumstances that prompt the voodoo beliefs at hand as immediate and obvious and, moreover, that there are no defeaters for these beliefs. But reformed epistemology is as such committed to neither of these claims and, hence, does not entail radical relativism.

Equality

Philip P. Taylor
Department of Political Science and International Affairs, Kennesaw State University, Atlanta
Kennesaw, GA, USA

Equality is defined essentially in four ways: Equality of opportunity, equality of outcome, social equality, and political equality. Equality of opportunity is everyone having the same chance at a desired outcome. Equality of outcome is ensuring that the desired result or outcome occurs. Social equality seeks to provide consistency and sameness in the distribution of wealth, property, education, and other resources. Political equality is typically understood as no one individual having greater influence or control over the government and its ultimate use of power.

Description

Eschatology (from the Greek *eskatos*, “what is at the end” or “last”) is the study of the final end of all things and the resolution of all creation in its ultimate goals. In fact, the long sweep of evolution, when studied from a theological point of view, may suggest a creation whose theological “goodness” may be viewed as fully accomplished only in the eschatological future. Although in the Christian theological tradition, the eschatology has a primary place, the idea of an *afterlife* is present – in a greater or lesser extent – in almost all world religions.

The only exception is Buddhism which, referring to a *beginningless samsara*, namely, the endless cycle of birth and death, states that it is not possible to say a “starting point” of the universe (as well as of the individual) neither an end of it. In this sense, Buddhism has in common with other Indian religions (particularly Hinduism and Jainism), the idea that the universe passes through an unending series of cycles of manifestation and non-manifestation. Buddhism speaks of an ultimate and final end only on the level of the individual (living) being: all the teaching of Buddha, in fact, is aimed to provide to his followers the resources in order to definitively escape from the *samsara*.

To achieve this goal, every believer must carry out a process of self-training that will lead it to a definitive enlightenment and a complete understanding of reality as it is, the experience commonly known as *nirvana*. By replicating the awakening of the Buddha, his followers too could finally escape from the painful process of rebirth.

Islamic tradition, on the contrary, not only speaks extensively of death, end of the world, and resurrection, but, according to the *Sunnite* tradition, eschatology is directly related to one of the six fundamental articles of the Islamic faith (seven according to the *Shiite* tradition). The Qur'an calls the end of this world (and the beginning of the next world) the "day of resurrection," in which the living God, the Most Merciful of the merciful, will descend in order to carry out an interrogation: people will be called one by one, and they will be asked not what they did, but why they did it. Consequently, the righteous will be rewarded with the pleasures of the heavenly life, while the unrighteous will be punished in the hell. The Qur'an, using colorful depictions as well, clearly claims that both the ultimate joys and sufferings, resulting from the divine judgment, make reference to deeper realities which are proximity to God, on the one hand, and distance from him, on the other.

Christian eschatology may instead be seen as a *dimension* inherent in all theological studies, orienting them toward an analysis and an understanding of the God's plan of creation and redemption through the study of the *future* prospects. This is the *last* (extreme, insuperable, and definitive but also inaccessible or only partially deducible) stage of the existence of individual beings, of the human race, and of the creation at all. Therefore, its main and primary task is not to know – in a comprehensive, descriptive, or even representative way – the *afterlife* or the realities *beyond* the death.

So considered, Eschatology cannot be defined only as the *science of the afterlife*: instead it is a daring hope, an attempt, a *provisional wandering*, and an approach to the *threshold* without ever reaching it. Any easy materialization of

eschatological realities must be avoided since they must be considered as "something" that happens or occurs without any participation by the involved *actors*.

Nevertheless, in the academic context, eschatology is treated quite literally and considered as an autonomous discipline which finds its place in the end of systematic area because it is related both to the belief that the *last things* are the final intervention of God in the history and to the reflection on the *Novissimi* – death, judgment, heaven, hell, and purgatory – and the final resurrection, with "new heavens and new earth" that follow on from it.

At the center of eschatology's concerns, there is not *the end* as such, but the end as the *new creation* of all things, that is to say both the conclusion of God's salvation plan – that encompasses the final destiny of all things – and the "return" of Jesus Christ at the *end of time*.

Consequently, three main features mark eschatology. First of all, it is a reflection on the individual and on the relationships between him and the *others* (the mankind and God). Secondly, it accounts the future in the light of the past, characterizing itself as a *theology of history* aiming at understanding – even more and even better – the meaning of human actions and their not always positive outcomes. Thirdly, it regards the *cosmic* perspective, which considers the man as *a part* of the creation and *inside* it, because his fate is strictly tied to it (Schwarz 2000).

Already in the ancient Indo-European traditions is possible to recognize an abundance of evidence for various beliefs about death and afterlife, but it is not possible to identify an original belief; from an anthropological point of view, the eschatological reflection stems from the human need to create an *order*, giving organization to every form of chaos. Human beings at a certain point of their evolution felt the need of a *structure*, even external, in order to think of and to say about space and time.

Hence, what Abraham J. Heschel called the "architecture of time" – the evaluation of time as a substantial dimension for Jewish (and, later, Christian) thought – can be seen as an ideal

foundation of the conventional division of the time flow into measurable and *structural* units (Heschel 2005).

If the *eskatos* is the word of God that *breaks* the silence of the human present *breaking into* it and stimulating a reflection on the *signs of the times*, which are not *continuous* but discrete and discretizable, then it is an announcement, it is the *good news* that cannot be set aside considering it as connected with a future *potential* and yet to come; rather, the *eskatos* must be seen as anticipated in the concrete instants of the present and, for this reason, as an “invitation” to a different future.

The Old Testament is not very clear about the contents of the Jewish eschatology, but it certainly underlines two polarities: the *expectance* and the *promise*. In fact, Israel is the nation that expects the realization of the promise made by God, what J. Moltmann calls the experience of the *not yet* that becomes, just *now*, a direction to take and to follow (Moltmann 2000). In recalling God’s actions, Israel remembers the *indefinable something* that makes it the *chosen people* and that, at the same time, in an even more painful way highlights its infidelities (and its betrayals) to this promise. God sets the future: the task assigned to Israel is to realize – in its present – the contents of that future.

Everything starts with the creation and will end with the *age* (not only with the *world*) that is yet to come: while the Hebrew word *olam* indicates both the “time” (more properly the “century”) and the “world,” *olam ha-bah* directly refers to a *new era* that is yet to come, qualitatively *other* and *different* from the present – the epoch of history – if not even its opposite. For the Jewish tradition, God is the Lord who establishes an end to the world and introduces a new era; He is the King, every believer observing the Torah may receive in his own life. Nevertheless, the full realization of His kingship belongs only to Him: the whole history is placed under the dominion and the judgment of the Most High.

In the Jewish tradition, the human concern for history, based upon the fact that everything has a beginning, finds its central point in an equally strong concern for the last things: if, in order to

understand *where we are*, we talk about the initial event (a fact we did not watch), in the same way we must try to define the final events, even if we will not witness them.

Subsequently, according to the Christian tradition, God is the Lord of all events in space and time; He is the Lord of creation and history. These ones, in turn, can be considered as marked by the faithfulness of God to His ancient and new promises. Furthermore, the Christian hope finds an additional eschatological foundation in the victory of Christ over the death: according to the Pauline literature, in the final times He *will gather* the whole creation *in one*, initiating a *novum* unattainable by human forces only and, at the same time, solving the *unde malum* question in new categories.

The NT eschatology arises from the need to set the initial and the final boundaries of the human experience of time, and it has a *utopian* feature: it corrects the imperfect nature of human life in the *here and now* and allows men to hope in an age wherein imperfections and defects will disappear. Gospels frequently return to this facet, insisting both on the value of the present and on the imminence of the end of times. The “waiting-promise” polarity, proper of Israel, once again is confirmed in Jesus Christ, who announces a kingdom to be waited – it surely *will come* in the future – but, paradoxically, *already present*: choosing Jesus Christ (thus operating a *decision*) in the years to come, the evoked future, *just now* can find a mode of action in the present history of every man, of the entire humanity, of whole creation (Vorglimler 1980).

In the last 50 years, the theological reflection has emphasized the uninterrupted presence, in creation, of both Christ and the Spirit – almost in a foretaste of that *eskaton* which will find its full and final stage in the future. In fact, the meaning and the value of things in the world consist not only of what they are or have been, but also of what they can become. The hope in the future, that the eschatology invites us to sustain, is not a wishful thinking, nor an easy expectation. Rather, it is *hoping against any hope*, moving in an obstinate and opposite direction compared to any apparently positive result, tracking down that

“something” unifying all mankind in the deep of its own being. On a cosmic scale, the eschatological hope arises when considering all the imperfections of this world, all faults that challenge us every day as well as all unfinished dimensions of our personal life. The ultimate hope is the eschatological hope: somehow and somewhere, there will be a time (and, perhaps, a place or, rather, a *non-place*) where all the imperfections, all defects, and all unfinished things will disappear.

Obviously, we should not forget that the eschatological language is a symbolic and mythic one, where the word *myth* keeps its original meaning standing for *word*, and then *speech*, recount, and *narrative*.

In this sense, along with the language on the last things, eschatology contains a reflection on the meaning of both history and the *absolutely ultimate* (a valuable asset in a more and more relativized world).

The prophecy, which is a hopeful expectation, encourages the witness and then becomes a lifestyle. For this reason, in Christ eschatology becomes relationship between the human life and the *eskaton* in its final form as fulfillment, and not a mere description of the *eskata*. “God hath raised up” him (Acts 2:24) and then He is present in the Church’s life and in the life of each believer. Consequently, the *here and now* can only be opened to the future and constitutively related to it. Therefore, the eschatological thinking brings together two asymmetric realities: the *historical future*, that is man-made, and the *future that comes*, work of God. In the middle of them is Jesus Christ, the only one who can reconcile this asymmetry and make up the opposites. He is the divine-human *eskatos*, the subject of the eschatology and not an element of it, He is the eternal Son who has chosen to come in contact with the cosmic-human reality because he wants to take it upon himself, in order to renew and heal it.

The eschatological dimension, rather than a *geographical* one, is an *historical* one – giving meaning to the present as it is seen projected into the future – and, even more, is a *teleological* one, because things will reach their end when they achieve the purposes for which God created them. The eschatological thinking, consequently,

pertains to the novelty inherent in the ultimate destiny of creatures and of all the creation: it attempts to, at least stammering, answer the Kantian question “What can we hope for.”

In brief, three elements can be found within the eschatological question: the ultimate destiny of the universe (the *universal* element), the whole humanity (the *collective* element), and every human being (the *individual* element) (Ratzinger 1977).

This last element is ignored by the so-called *scientific eschatologies*, especially the most recent of them, which, starting from the (scientific) cosmological idea of a universe *open* that will continue to cool and expand forever, claim that these characteristics will have an impact on all the structures that compose it, from galaxies to living organism, which will vanish forever without a trace (Polkinghorne and Welker 2000).

Nevertheless, the *individual* element, it is indeed in the heart of the Jewish-Christian tradition which, however, is also concerned about the fate of both the elementary particles and the macroscopic elements of the universe. However, while the fate of the universe, when scientifically analyzed, is considered as oriented in a completely deterministic way (the universe began its growth probably with the Big Bang and will continue its course, come what may), the Jewish-Christian tradition sees the end of all things as an initiative that arises solely from the will of God.

In this sense, sciences can offer many significant contributions to theology: biology, paleontology, geology, and astronomy can in fact help to value both the *contingency* of the existing things (recalling that the created things will not exist forever) and the perennial *novelty* of the things created in nature.

Reflecting on the final perspectives of the cosmos, religion and science can both learn how to cope with a reality that is literally *beyond* any possible human experience. On this aspect, and without any reductionism, it is possible to state that, trying to explain the observable world, both religion and science make reference to an unseen world. Pursuing the ultimate description

of what is immediately visible they choose – and postulate – a world that is invisible and, at the same time, is the reason for which things are as they are.

Esotericism or Esoterism

Catharina Stenqvist
Centre for Theology and Religious Studies,
Lund University, Lund, Sweden

A term with two basic meanings. In the dictionary sense of the term, it signifies the holding of esoteric opinions, and derives from the Greek *esôterikos*, meaning “within,” thus “pertaining to the more inward,” mystic. In the scholarly literature, the term designates a series of historically related religious currents including Gnosticism, Hermetism, magic, astrology,

alchemy, Rosicrucianism, the Christian Theosophy of Jacob Böhme and his followers, Illuminism, Mesmerism and Swedenborgianism, Spiritualism, and the theosophical currents associated with Helena Blavatsky and her followers. There are competing views regarding the common traits uniting these currents, none of which involve “inwardness,” mystery, or secrecy as a crucial trait. *Esoteric* knowledge, in the non-scholarly sense, is thus that which is available only to a narrow circle of “enlightened,” “initiated,” or specially educated people.

[Moral philosophy](#); [Morality](#); [Philosophical ethics](#)

Ethics is a lively field of argument, exploration, and creativity that thrives today because of the history of science and religious contention in the European context and the perpetuation of alternate versions of a good life in cultures worldwide.

The term “ethics” is categorized in several characteristic ways. First, ethics can designate actual conduct and character, and the principles, values, and rules that people use to regulate themselves and their relationships in small social settings or large social, economic, and political networks. Discussion of ethics in this sense is often descriptive, although it may verge into prescription, that is, views about what conduct and character ought to be. In formal academic settings, anthropology, sociology, psychology,

and religious studies may engage in descriptive study, although they often explicitly reject any effort to prescribe what ethics should endorse. A second category for understanding the term “ethics” specifies the systematic and reasoned study of right conduct and good character as essential elements of a good life. Ethics as elaborated in these endeavors is primarily “prescriptive,” aimed at specifying what character and conduct and their bases in thought and human life should be (Korsgaard et al. 1996). For this meaning, “moral philosophy” and “philosophical ethics” can be used as rough synonyms, although theology and religious teachings may also speak systematically to the good and the right in individual and social human existence.

These categorizations of ethics permit three limitations on the present discussion: First, ethics in philosophy is so broad that reflection on ethics in non-European religions and philosophies would require a separate entry. Second, particular codes of professional ethics are a subset of prescriptive ethics. An appeal to professional ethics alone as a justification for action is unlikely to satisfy the range of ethical considerations. Rather, professional ethics depends on the wider discussions outlined here. Third, ethics as discussed here readily encompasses morals, sometimes defined as specific prescriptions for behavior and virtue. Some writers distinguish between “morals” so defined and “ethics” delineated as the conceptual bases for morals. While clarification of these aspects of thought about ethics is helpful, experts’ terminology for conceptual bases and actual prescriptions may vary from this nomenclature.

Three standard approaches to moral philosophy are character-oriented, teleological, and deontological ethics. The deontological focuses more on prescriptions of duty than on outcomes of action. The teleological emphasizes attaining the right goal (Greek *telos*) of action or character. Utilitarians have dominated the nineteenth- and twentieth-century teleological discussions of action, while the character-oriented approach comprises a full field of inquiry. Character ethics may also be referred to as “aretic” ethics from the Greek *aretē*, meaning excellence.

Character ethics takes Aristotle’s *Nicomachean Ethics* as its preeminent reference point for expanding on ancient Greek philosophy. Aristotle conceives of good character as directed toward the *telos* of a happy life. Dispensing quickly with fame and wealth as happiness (Aristotle 2002, I.5), Aristotle expands on the notion that happiness is “activity of soul in accordance with virtue.” In this instance, virtue is the human soul’s particular excellence, which is its ability to use reason properly (Aristotle 2002, I.7). Proper use of reason will guide the appetites or passions to a mean between extremes. Reason thereby allows the person to control the passions or appetites rather than being subject to them (Aristotle 2002, II.6). Good conduct shapes virtuous character and in turn flows from it as a person matures (Aristotle 2002, II.2). If the soul can achieve virtue, Aristotle says, happiness and a good life can be assured, independent of chance, except in extreme conditions (Aristotle 2002, I.9).

Aristotle’s writings directly influenced ethical thought in Western Europe for several centuries and then indirectly through other thinkers’ treatises, until, by the middle of the thirteenth century, Latin translations made his own works familiar again. In the thirteenth century, Thomas Aquinas wove Aristotle’s ideas explicitly into moral theology in the then dominant Roman Catholic Church (Hare 2008). Also in the medieval period, Aristotle heavily influenced Muslim moral theology and encyclopedic Jewish thinkers like Maimonides.

Aquinas’s theological ethics with its Aristotelian structure was weakened, however, by armed conflict between Catholic rulers of Europe and Muslim powers from its south and east, violent challenges to Catholic dominance during the Protestant Reformation of the sixteenth and seventeenth centuries, and rise of modern science. The violence alienated many Europeans from any religious ethics. Scholars were impressed by scientific advances and sought to give ethics a nonreligious grounding, composed more exclusively of claims to reason. Justification of ethical prescriptions by appeals to the authority of the ancients and biblical revelation was undermined.

One response to the chaos of the sixteenth and seventeenth centuries was the deontology of Immanuel Kant, the eighteenth-century Prussian philosopher with whom twenty-first-century philosophers must still contend. Kant is best known in ethics for his “categorical imperative,” his formulation of a command that applies no matter what else must be considered: “Act only according to that maxim by which you can at the same time will that it should become a universal law” (Kant 1785, p. 38 [421]). Kant appears to believe that careful examination of the ideas so stated yields a second form of the same imperative: “Act so that you treat humanity, whether in your own person or in that of another, always as an end and never as a means only” (p. 46 [429]). Briefly recapitulated, the second form enjoins us to weigh our proposed actions against the consideration that every person is a worthy aim of action, is someone whose well-being is worth promoting. Yet a third statement of the categorical imperative, according to Kant, affirms “the Idea of the will of every rational being as making universal law” (Kant 1785, p. 48 [432]).

Despite challenges to them, all of Kant’s formulations of the categorical imperative have reached far into world thought. In addition to applications of the first form to daily life, they have influenced notions of the just formation of political entities. For instance, participatory forms of government are required by the conceptualizations that people are ends in themselves and not just means to political ends and people are capable, with education and thought, of giving themselves laws based on reason. The imperatives also speak to human and civil rights and to the specification of those rights through limitations on research on human subjects in science. These limitations often derive from questions like, “Could this or that scientific treatment of a person be a universal law? Would it treat the person as only a means to an end?”

The best-known teleological approach emphasizing conduct is utilitarianism. Utilitarianism has its roots in the philosophy of Epicurus (341–270 B.C.E.) and developed through the writings of the eighteenth-century Scottish philosopher David Hume, the British philosopher

Jeremy Bentham around the turn of the nineteenth century, and his friend’s son John Stuart Mill, author of *Utilitarianism*. Mill makes a case for the principle of utility as the basis for all further moral judgments. He presents the utilitarian movement as holding that conduct is right as it tends to promote pleasure and minimize pain, when moral reflection accounts for the largest number of sentient beings affected by the action. He insists on utilitarianism’s accordance with biblical teachings, without letting any religion displace utilitarianism as the ground for ethics (Mill 1861, ch. 2). Although utilitarians often note that pleasures and pains can vary and philosophers disagree about whether to maximize goods different from pleasure, utilitarian reasoning today has major philosophical proponents, like Peter Singer (Singer 2002).

Philosophers arguing for deontological or teleological approaches to conduct, like exponents of character before them, often seek certainty in the idea that human nature has universal aspects that would ground ethical principles for all human beings. Yet their conceptions of the nature of human beings, their downplaying of religion and ancient systems of thought, and their preference for universals have all produced sharp criticism of and alternatives to the three major approaches. For instance, three intellectual giants of the nineteenth and early twentieth centuries now affect notions of human nature in ethics. Karl Marx points out unacknowledged effects of wealth on moral philosophy and judgments (Marx 1978). Friedrich Nietzsche concentrates on the unacknowledged role of power in ethical thought and action (Nietzsche 1998). Sigmund Freud highlights unconscious desires, especially sexual ones, in the origins and later judgments of ethics (Freud 1990). These challenges form the bases of many postmodern critiques, such as those from postcolonial theory and deconstructionism, of the three standard approaches to ethics.

Two outstanding and strikingly different criticisms from within the twentieth-century philosophy speak to previous conceptions of reason and ancient philosophical systems. Michel Foucault challenges the eighteenth- and

nineteenth-century conceptions of human reason as fundamentally a function of individual thought, independent of the workings of societies. Alasdair McIntyre brings Aristotelian thinking back to prominence in *After Virtue* and argues that philosophical ethics must acknowledge its dependence on the ways of life in which people find themselves, much as ancient Greek philosophy formulated its moral judgments with reference to the accepted practices of its day.

Alternatives to the three standard approaches often emerge, perhaps unexpectedly, from the emphasis of the eighteenth- and nineteenth-century philosophical ethics on the universality of its conclusions. People previously excluded from discussions of philosophical ethics began to argue that moral claims aspiring to universality would have to attend to experiences and activities that European male philosophers and their heirs ignored or derogated. Collaboration of women, especially in philosophy and psychology, on ideas and practices of caring has produced a major strand of investigation in ethics. Similarly, formerly colonized peoples have advanced ethical proposals from the perspective of their peoples' traditions. Scholars of religion and anthropologists have promoted these discussions and been challenged by them. From these efforts emerge ethical arguments that value highly religious practices and texts, non-European customs, and the natural universe (e.g., Sullivan and Kymlick 2007).

These lines of inquiries do not exhaust the field of ethics. Many moral philosophers and theologians treat the relationships of ethics to metaphysics (ideas of what must be true for the world to appear to us as it does). They may debate epistemology, our ability to know the bases of ethics and draw conclusions even without complete certainty. Scholars of ethics search the natural sciences and the social sciences for evidence of what is possible for human conduct and character and for description of situations calling for ethical reflection. And always the arts and cross-cultural and historical studies of actual ethical systems challenge claims to ethical certainty and propose visions of a good life to unsettle and inspire reflection, character, and action.

Ethics/Moral Theology, Roman-Catholic, Europe

Walter Schaupp

Department of Moral Theology, University of
Graz, Graz, Austria

Self-description

Roman Catholic moral theology is a subdiscipline of Catholic theology in general. It seeks to describe, critically analyze, and methodologically justify the implications of biblical revelation for the Christian conduct of life: How one is to act or behave in the light of the Christian faith, according to the Bible and in consonance with Catholic tradition and doctrine? Throughout the patristic and scholastic period, moral theology was an undifferentiated part of Christian theology and it was only after the Council of Trent (1545–1563) that it developed as an independent discipline. It is generally divided into fundamental moral theology (*theologia moralis fundamentalis*) and special moral theology (*theologia moralis specialis*), the first including questions of ethical theory, individual conscience, sin, and remission; the second is equivalent to the different topics of applied ethics.

Since its beginnings, Catholic moral theology as a religious ethics encompasses a strong tradition of natural law. Man, as a creature of God endowed with freedom and reason, is capable of having insight into a natural moral order, called natural moral law (*lex naturalis*). This leads to the assertion of a twofold source of moral insight – supernatural revelation and nature and natural reason –, founding two, partly overlapping spheres of moral truth, i.e., natural and

supernatural moral law (*lex naturalis* and *lex supranaturalis*). As a consequence, it is typical for Catholic ethics to mediate between theological and philosophical, religious and secular notions and descriptions.

Recent Developments in Europe

Catholic moral theology in Europe has undergone a renewal under the impact of Vatican Council II (1962–1965), and German theologians have played a prominent part in it. Already before Vatican II, after a long period of neoscholasticism, characterized by rationalism, legalism, casuistry and high inner theological uniformity, a reception of existentialistic and personalistic thought, as well as a general desire for a more existential and spiritual outlook, led to a fruitful period of new accounts, commonly known as “christocentric moral theology,” e.g., Bernhard Häring’s “Das Gesetz Christi” published in 1954. A more decisive breach, by no means concurrently in all European countries, occurred after Vatican II, when Catholic moral theologians like Josef Fuchs, Bruno Schüller, Franz Boeckle, and Alfons Auer tried to lay new foundations for their discipline. For some decades, discussions centered on questions of normative theory and metaethics. Schüller (1973) tried to show that the Christian commandment of love is compatible with a modified consequentialist model of ethics rather than with traditional natural law theory. Auer (1971), stimulated by the inner church crisis that had been provoked by the promulgation of the encyclical *Humanae Vitae* (1968) on artificial conception, developed the model of Autonomous Morality. His ethical account advocates the freestanding authority of human practical reason in the secular moral sphere (“Weltethos”), in contrast to the Catholic magisterium whose genuine and exclusive competence is seen in questions of faith and praxis of faith (“Heilsethos”). The debate that followed is known as the controversy on the *Christian proprium* because – according to Auer – Christian faith does not give an extra

insight into moral problems beyond natural practical reason (instead of this, it motivates and stimulates rational insight and ethical behavior). Some assertions of Auer and Schüller have been subsequently rejected by Pope John Paul II in his encyclical *Veritatis Splendor* (1993). In spite of such controversies, Auer's and Schüller's work has deeply influenced post-Vatican European moral theology. Apart from this, the post-Vatican period has been marked by ongoing conflicts between the Roman magisterium and moral theologians in the field of sexual ethics (artificial contraception; AIDS and condoms; homosexuality; divorced and remarried Catholics).

Today European moral theology exists in a plurality of different theoretical approaches. This is due above all to divergent philosophical positions theologians are in dialogue with, to an asynchronous development of theology in Western and Eastern European countries, to language barriers (German- vs. Romanic-speaking regions), and also to some tendencies to restore classical, neoscholastic thinking. Nevertheless, there are common challenges that foster dialogue and communication between theologians: the ecological crisis, the growing secularization of the European societies, legalization of active euthanasia and same-sex marriages in some European countries, and a wide range of biotechnological challenges.

Under the influence of the encyclical *Evangelium Vitae* of Pope John Paul II (1995), there has been a general turn to life-questions in the Catholic Church. Catholic moral theology in Europe as an academic discipline took part in the evolving bioethical discussion in Europe (Korff 1998) and many moral theologians became members of ethics-committees or were involved in the teaching of medical ethics. Also feminism had an impact on Catholic moral thinking, although less than in other theological disciplines, e.g., exegesis, and not as productive as in the Anglo-American world.

There have been considerable ecumenical efforts between Catholic and Protestant ethicists during the last decades of the twentieth century as the ecumenical "Handbook of Christian

Ethics" (Hertz et al. 1978–1982) shows. After a period of consensus, however, differences are reappearing in the field of life-ethics (e.g., positions on embryonic stem cell research) and recently Protestant theologians are propagating an "ecumenism of difference." While Catholic moral theology favors objective moral truth and moral judgments, Protestant theologians commonly emphasize individual conscience and responsibility and the necessity of moral compromise. Because of this and the absence of an authoritative magisterium, moral positions within the evangelical and protestant churches are more heterogeneous than Catholic positions are.

Self-identification as a Science and Questions of Epistemology and Methodology

In the course of the last century, Catholic moral theologians have become more and more aware of the necessity to clarify epistemological and methodological questions in confrontation with modern science and philosophy. At the first step, Catholic moral theology identifies itself as an ethics with a cognitive, normative, anti-relativistic, and universalistic outlook. As such, it goes beyond approaches that want to give scientific explanations to or mere descriptions of the phenomenon of morals (e.g., evolutionary ethics, neurobiological ethics, studies of moral systems within cultural anthropology), but also differs from individual ethical subjectivism. In contrast to philosophical ethics, it not only refers to human reason but also to particular religious beliefs as a source for ethical reasoning. As a consequence, one of its most challenging theoretical problems is how to integrate the two sources of knowledge, natural human reason and supernatural belief (divine revelation), in an all-encompassing theory.

According to Klaus Demmer's (1985) transcendental-hermeneutical approach, value claims and normative judgments are derived from a two-stage interpretation of factual (empirical)

judgments: interpretation of *facts* on a (philosophical) *anthropological* level (e.g., exploring the notion of human freedom on the basis of neurobiological facts) and interpretation of *anthropological* “truths” in the light of *religious* beliefs (e.g., exploring the notion of human freedom in the light of faith). According to Demmer, we therefore are confronted with three levels of truth-claims, namely, factual, anthropological, and theological, which are related to specific methods and standards of verification and which, together, constitute the epistemological background for the inquiry of moral theology (articulating the *value* of human freedom and correlating moral *norms* in the light of faith). Another approach holds that a narrow set of basic, universalistic norms can be demonstrated by convincing rational arguments (e.g., by some type of transcendental argument), whereas other moral claims emerge from an interpretation of human traits in the light of particular religious beliefs; e.g. Schockenhoff (1996).

Religious sources of authority are the Bible, authorities of the ecclesiastical and theological tradition (above all Augustine, Thomas Aquinas, Francisco Suarez, Francisco de la Vitoria, Alfons Liguori), and magisterial documents (Vatican Council II, encyclicals as *Humanae Vitae*, *Veritatis Splendor*, *Donum Vitae*). Philosophical sources are predominantly Aristotle and Kant, then representatives of personalism and phenomenology, and, recently, Jürgen Habermas. Utilitarianism is normally seen as in conflict with core assumptions and values of Catholic ethics with its strong deontological tradition. Particular natural sciences and humanities are indispensable interlocutors to the moral theology but never as immediate source for normative claims.

Future Challenges

For a long time, post-Vatican Catholic moral theology in Europe has concentrated on metaethical questions and on the field of applied ethics has

been involved in discussions of bioethical problems (e.g., status of the human embryo, stem cell research, end-of-life decisions). Ecumenical efforts mainly involved the protestant churches. In the future, moral theology will have to deal more with questions of the good life and with virtue ethics. It will have to strengthen its biblical and genuine theological profile in the context of a secular and multicultural society, also in critical dialogue with other religious traditions. On the other hand, moral theology will have to defend certain universalistic moral claims, based on human dignity and human rights, with a special sensibility for of all kinds of vulnerable groups within modern society.

Description

Ethnology is the study of humans as cultural beings. It explores how cultural patterns are constructed, preserved, and changed in various times, places, and social contexts. Peoples' cultural behaviors and expressions are examined through both contemporary analysis and historical reconstruction. Qualitative methods dominate and the empirical material is derived from various sources, such as archives, interviews, observations, questionnaires, artifacts, print and nonprint media, or the Internet.

The term "ethnology" derives from the Greek *ἔθνος* (*ethnos*) meaning people. As defined in various ways, the subject has developed along separate paths of inquiry and pedagogical principles (i.e., social and cultural anthropology and folkloristics). Ethnology (or folklife research) has been considered an academic field since the late eighteenth century, with professorships established mainly during the first half of the twentieth century. Being a child of its time, ethnology was then part of the construction of "folk" or "national" cultures. Ethnologists in their respective national

settings were engaged in preserving and presenting their unique heritage. Still there were incitements for international perspectives and cooperations. The overall methodological approach was comparative with close links to general anthropological theories of evolution and diffusion.

More or less explicit uses of ethnology/anthropology by Nazism, Fascism, Stalinism, and colonial expansionism have subjected the discipline to external and internal criticism (Craith et al. 2008). One significant consequence of the postwar critique is the strengthening of the particular characteristic of ethnology as "history from below," i.e., with focus on overlooked categories of people and cultural expressions (see section "[Characteristics](#)"). Another result is the move away from essentialist, homogenizing and deterministic understandings of culture. Scholars such as Arjun Appadurai, Fredrik Barth, and Ulf Hannerz (Hannerz 1992) have called attention to globalization, to ethnicity as social construct and culture as flow. Social constructivism is a common theoretical basis, generating studies on images, categories, norms, and values of people as individuals and/or as members of social groups (Berger and Luckmann 1967). In combination with structuralism, interactionism, and phenomenology, social constructivism has made scholars like Pierre Bourdieu and Erving Goffman particularly influential in the field. Researchers associated with structuralism, with major importance for the study of cultural and religious myths and rituals, are Claude Lévi-Strauss, Mary Douglas, and Victor Turner. Engagement in the work of Michel Foucault, and other leading names of the "linguistic/narrative turn," has led to a boost for discourse analysis and the focus on culture as representation. Further, the complex relation between the researcher and the researched has been discussed in what has been labeled as the "reflexive turn" (Marcus and Fischer 1986). This is both epistemological and political, and does not only concern the concrete meetings between the researcher and the researched, but also their dynamic interplay with structures and conditions of life. In the wake of the latest decades'

minority struggles (i.e., indigenous and colonized people, people of color, women, and nonheterosexuals) ethnologists add self-reflexive knowledge about the maintenance of asymmetrical power relations. Ethnology is a science which contributes to society's reflection over itself. This ambition is indicated in the review of study programs in ethnology published by the Swedish National Agency for Higher Education in 2008. Here the reviewers encapsulate the ethnologist's special competence to:

- concretely illustrate everyday processes from the perspective of different groups;
- let the mundane and the seemingly normal appear less self-evident;
- examine prejudices and stereotypes critically;
- make the strange and the unfamiliar more comprehensible;
- understand why misunderstandings and conflicts appear between people, and how to counteract and avoid such tensions;
- analyze how technology and media shape people's daily life;
- study how old traditions, rituals, and perceptions linger in modern life – and how new ones are created;
- reflect on present times from a historical perspective, through the investigation of how dreams about the future or the longing for the past constitute the present.

Self-identification

Science

Ethnology identifies itself as a subject within the humanities. It draws on empirical studies, with predominantly qualitative methods. Although being a subject within the humanities, it is still closely linked to social sciences, its sister-discipline anthropology among others, which is generally categorized as a social science.

There is an increased call for ethnologists to participate in interdisciplinary studies of science, i.e., natural science, technology, medicine, and environmental research. Here the objective of the ethnologist's involvement is twofold: On

the one side it adds knowledge about individuals' and groups' perceptions, practices, and needs in relation to those domains; on the other, it scrutinizes science as a cultural product in itself. Ethnologists have developed productive tools for the study of the dynamic interplay between culture, society, and science, with particular focus on the construction, dissemination, maintenance, and change of meaning, knowledge, and truth (Reid and Trawick 2000). Cutting edge research is often coming from feminist theoreticians, such as Emily Martin and Donna Haraway (Haraway 1997), well aware of gendered postulations and division of scientific labor. Critical studies on processes of "naturalization" of beliefs and practices are mixing with the growing interest for biology and brain research.

Religion

Ethnology does not identify itself as a religion. It embraces the study of popular religious beliefs and practices. As concisely phrased by professor of ethnology Gábor Barna:

The subject of the research carried out in different countries under various names (religiöse Volkskunde, Volksfrömmigkeitsforschung, ethnology of religion, anthropology of religion, etc.) is essentially the same: so-called folk religiosity or popular religion supplementing the practice of dogmatic religions, the everyday practice of religion and, in general, an ethnological/anthropological approach to the study of religious life. (Barna 2004)

Ethnologists aim at understanding the ideas and experiences of the people they study. Their intention is to attain both the "emic" (insider) and "etic" (outsider) perspectives. The people studied are increasingly regarded as "subjects," i.e., "participant observers" as well as the researcher, who acquire knowledge about the social world in the course of participating in it. Thus, the participants' accounts can be analyzed "in terms of the perspectives they imply, the discursive strategies they employ, and even the psychosocial dynamics they suggest" (Hammersley and Atkinson 2007). This means that the ethnologist's analysis does not simply attempt to replace peoples' religious beliefs with

cultural or sociological explanations. There is indeed space for the study of experiential aspects of religion, cultural phenomenology, and embodiment (Csordas 2002). Religion in relation to medicine and health is constantly an important ethnological field. Today much interest is oriented toward the role of religion and the changes in the (late/post) modern society. Secularization, migration, identity, gender, and youth are frequent themes.

Characteristics

Ethnology is a cultural science within the humanities, closely related to social and cultural anthropology and folkloristics. In Sweden, folkloristics has merged with ethnology, while in countries such as Finland and the USA, it is organized as an independent discipline. Tradition has it that anthropologists focus on non-Western cultures and ethnologists on culture “at home.” In the wake of globalization and transnational migration, the distinction between the disciplines is increasingly blurred. Despite common roots, ethnology and anthropology are being categorized and positioned differently within various national academic organizations. From a Swedish horizon, the following features contribute to make this discipline distinctive over time and in relation to other (sub)disciplines: the ethnographic method; the combination of synchronic and diachronic perspectives; the eclectic approach in theory, methodology, and empirical material. Last but not least is the firm focus on everyday life:

In the academic division of labour, ethnology emerged as the discipline of the overlooked or ignored, the seemingly trivial – all that the historians found too mundane, the aesthetic expressions art historians defined as too popular, the narratives that did not qualify as literature and the everyday routines that did not interest the sociologists. (Löfgren 2008)

Relevance to Science and Religion

Ethnologists have developed productive tools for the study of the dynamic interplay between

culture, society, and science as well as between culture, society, and religion. Although little attention has been paid by ethnologists to the emerging field of “science and religion,” such a fusion might be viable and rewarding.

Sources of Authority

The ethnologist’s sources are not given a priori, but need to be “created” by the researcher through the collection of various empirical data (i.e., interviews, observations, artifacts, print and nonprint media). Worth mentioning are also the large national archives and collections accessible especially in the Nordic and Baltic regions, including material on faith and religious customs. The work does not aim at natural scientific evidence, but at analysis and compelling argumentation along with authoritative management of all steps in the research process from experience to text. The overall purpose is to present various and substantial perspectives on given cultural and societal phenomena. Ethnology is known for being eclectic in both methodological and theoretical approaches. The basic attitude is often that of cultural relativism, with less of an obsession with canons, and more preoccupation with critical self-reflections over how such standards are used as means to produce and reproduce hierarchies and precedence of interpretation. Contemporary ethnologists gain authority through peer review procedures, but also through high quality semipopular scientific publication/interaction.

Ethical Principles

Like any other scientists, ethnologists are guided by correctness, sincerity, and responsibility. The particular ethical dilemmas intrinsic to ethnological research are dealt with in various codes of ethics, for example, the American Anthropological Association’s statements on ethics (<http://www.aaanet.org/stmts/ethstmnt.htm>) and UNESCO’s code of conduct for social science research (http://www.unesco.org/new/fileadmin/MULTIMEDIA/HQ/SHS/pdf/Soc_Sci_Code.pdf).

Key Values

A key ambition is to give people tools to better understand themselves and the world.

Relevant Themes

Some ethnologists are involved in interdisciplinary studies of science, and many in the research on the interaction of culture and religion, with specific focus on popular religious beliefs and praxis. So far, however, ethnology has not directly dealt with the emerging field of “science and religion.”

Cultural turn

By European Studies we mean, on the one hand, the investigation and analysis of the complex relationships between history, culture, economics, law, and the social structure of Europe and, on the other hand, interdisciplinary courses of study, which in the last year have been introduced at numerous European universities. These courses of study both address and develop further certain questions and topic areas, which since the nineteenth century have constituted a significant portion of the European cultural sciences. The reasons for the introduction of these courses of study in Europe as well as on other continents are multifaceted.

As a result of the “cultural turn” in the humanities since the 1980s, the concept of culture increasingly has replaced the concept of society as the leading theme in the human and social sciences. Reflected in this trend is the recognition that religious cultures under modern conditions have not lost their capacity to leave their mark. Another important motive for the establishment of European Studies lies in the broadening of the European Union. The debate over admission of new member states into the European Union since 1989/1990 from the beginning was obviously as well about Europe as a cultural,

economic, and political unity. The newly admitted states are not only characterized by different religious traditions, but also by the degree of modernization unfolding in these countries based on different political, economic, and religious factors with varying development dynamics.

In addition, since the Second World War, there have been various waves of economic migration, so that the different European societies have become immigrant societies. As a consequence, European religious cultures have also become pluralistic. At present Islam in its different forms is the demographically largest non-Christian religion in Europe. These developments make it increasingly clear that Europe has no fixed essence, but is a rarefied cultural construct in which geopolitical, economic, legal, and religious elements are superimposed over it. The subject areas of European Studies are with regard to the indicated complex character of Europe exceedingly heterogeneous and many-sided. They encompass history, law, economics, politics, sociology, cultural studies, literary studies, linguistics, theology, and religious studies. In the current debates about Europe and European integration, the cultural influence of the different religions is given enhanced attention.

Religious characteristics do not function merely as markers of identity, but serve as cognitive maps of the world for people. Exclusion and inclusion are instrumental in the definition of religious membership, even if the traditional “inner-outer” boundaries of Europe’s dominant Christian creedalism have dissolved. In European religio-political discourse, there is currently heated and occasionally emotion-laden discussion about the integration of Islam into European society as well as the controversial admission of Turkey into the EU. In contrast with earlier debates, the discussion about ethnicity has been replaced with the invention of Islam as an identity marker or a political category (the Muslim Council of Britain, the Islamic Conference in Germany, etc.). Because of the many-layered topic and focus areas of European Studies, these discussions can only be conducted at an interdisciplinary level.

Finally, strengthened culturally oriented studies cannot help but join together different methodological approaches. The analytical interpretation of modern religious cultures demands the close engagement of cultural and religious theory as well as social scientific, legal, and political methodologies, in order to succeed and trace appropriately the transformation of religion and society in modern Europe.

Evil, Problem of

Thomas Anderberg

Department of Philosophy, Uppsala University, Uppsala, Sweden

Related Terms

[Moral evil](#); [Natural evil](#); [Theodicy problem](#)

Introduction

The problem of evil, also known as the theodicy problem (from *theos*, Greek for God, and *dike*, justice), is a conundrum, or rather a set of interrelated problems, with ancient roots. A very early, but still valid, wording is Lactantius' (c. A.D. 260 to c. A.D. 340) rendering of the formulation claimed to be by Epicurus (342–270 B.C.):

God either wishes to take away evils, and is unable; or He is neither willing nor able; or He is both willing and able. If He is willing and unable, He is feeble, which is not in accordance with the character of God; if He is able and unwilling He is malicious which is equally at variance with God; if He is neither willing nor able, He is both malicious and feeble and therefore not God; if He is both willing and able, which is alone suitable to God, from what source then are evils? or why does He not remove them? (Quoted from Ahern 1971)

However, the set of problems is somewhat wider than implied by this. Broadly, it consists of two separate but interrelated questions: (I) *the question of natural evil*, namely, why is there suffering in a world supposedly governed by a good and powerful god? and (II) *the question of moral evil*, namely, what is the justification, if any, of malice, greed, and cruelty in a world ruled by a benevolent Creator and superhuman Master?

The problem of evil has attracted massive attention during the centuries and is generally thought to be the most important objection to the credibility of theism, although there is no lack of answers brought forward by believers.

Evil

- [Sin \(Vice, Human Limits, Negativity\)](#)

History and Some Preliminaries

The problem of suffering appears in different guises in most religions. In Hinduism, suffering is seen as “the essence of the universe” (Bowker 1970), partly understood as a result of a power struggle among the deities. In Buddhism, too, suffering is thought to invade almost every aspect of human life. In both religions, the way to handle evil is primarily by efforts to become detached from ordinary ambitions and strivings. Accusations against heavenly powers are less frequent.

In Judaism, however, such accusations appear quite early, e.g., in Job’s book, although here, it is not the *fact* of suffering that is questioned but its *distribution*. God is believed to participate in history, and, consequently, it is natural to ask why God does not intervene more often, not least in order to alleviate the suffering of His people. In Christianity, the questions of suffering are not so much part of the sacred scriptures as of the theological discussion from Origen onward. Famous participants in the discussion are St. Augustine and Thomas Aquinas. With growing impact, well-known philosophers such as Spinoza, Hume, and Kant have written about it. The term “theodicy” (“*théodicée*”) was probably first used by Gottfried Wilhelm von Leibniz in 1697.

Concerning (I), the problem of natural evil, there are at least two questions brought up for scrutiny. (i) Why is there suffering at all? Why must human beings, or sentient beings, endure pain of the flesh as well as of the soul? (ii) Why is there no obvious proportion when it comes to which persons are stricken by these afflictions? Some individuals seem to encounter more pain than others, both short term and in the long run. This is not fair in itself, and when moral considerations are added, this injustice is apparently augmented. Some people who are morally good seem to suffer a lot, whereas others, who are less good, enjoy a prosperous life.

When the unfairness of this is brought up in the context of monistic religions such as Judaism, Christianity, and Islam, we have an example of the problem of *moral* evil. In monistic religions,

God is not only thought of as the Creator of the world but also as a supernatural person with qualities found in human beings, although elevated to perfection, and moral evil is not part of a set of properties that one expects to find in a perfect being. Human beings are created in the likeness of God (► *Imago Dei*), but they have deficiencies in knowledge and power that God does not have, and these weaknesses may be held to (at least partly) explain human moral ineptitude. These shortcomings are not found in God, and the question as to why God inflicts suffering on sentient beings, or at least abstains from removing this suffering, lays the ground for the theodicy problem.

The Theodicy Problem Posed

The problem itself can be simply formulated as follows:

- A. God is powerful to an immensely high degree (sometimes expressed more unguardedly as “almighty” or “omnipotent”).
- B. God is benevolent to an immensely high degree (sometimes expressed as “supremely benevolent”).
- C. God knows everything that is going on in the world (sometimes expressed as “omniscient,” which by implication also includes that He knows what is going to happen, at least in the near future).

If this is how God is supposed to be, then it seems to follow that:

- (a) If God is thus powerful, then He could abolish evil if he wants to do so.
- (b) If God is this benevolent, then if He would want to abolish evil, He could do so.

However, (D) there is evil in the world.

Hence, the Being presented in (A)–(C) cannot exist.

Therefore, God must be made up of other properties.

But a god that is weak is not how God is supposed to be; likewise, a being that is lacking in moral goodness is not God nor is a being that does not know what is going on in the world.

It follows that in the face of evil, there cannot be a god as generally conceived.

Due to the force of this line of reasoning, many claim they cannot believe in God. This, in turn, may be interpreted to the effect that the objector finds God lacking in moral aspects, which is a hindrance to worship Him. Alternatively, it may be interpreted to mean that God cannot exist at all and so should be wiped out of the set of valid beliefs.

Some Preliminary Responses

Nevertheless, as it stands, this formulation has shortcomings that can be pointed out by the theist (i.e., for thinkers that are concerned with doctrines seen from within a religious tradition). Some have tried to solve the problem by retaining the sum of God's properties (i.e., A–C) while rejecting the existence of evil, i.e., premise (D). This may easily be rebutted, for example, by pinching the objector and asking if the treatment should be prolonged or not. It may then turn out that what the objector claims is really that natural evil serves some further good, an argument that belongs elsewhere and will be discussed in section "[Responses Concerning the Omnipotence of God](#)".

Another possible reply concerns modifications of premise (C), God's alleged omniscience. One way to justify God is to ascribe God two different roles, i.e., the role of Creator and the role of Sustainer of the world. Some, like Voltaire, held the view that the creation was good although God later turned His back to it all. This, however, is a less promising route of defense since God in this fashion seems to have acted callously or nonchalantly when faced with the suffering of His creatures. The alternative view that God was later introduced to a world that already included suffering may, although it lacks scriptural support, seem more attractive, although it then becomes cloudy *how* strong God really is. Is God able to hear our prayers and put everything right in the end? Questions such as these are relevant also when one is confronted with the Manichean view of a competition concerning the power over the world between good and evil powers.

However, these lines of defense are not very promising and are also uncommon in the theodicy debate. Henceforth, the discussion will mainly deal with premises (A) and (B).

Responses Concerning the Omnipotence of God

Although the theist Richard Swinburne claims that "no writer who could plausibly be called a Christian has denied the omnipotence of God until this century," the omnipotence of God is far from clearly stated in the Scriptures and may even be incomprehensible as it stands. The Greek word "pantokrator" is sometimes understood to mean "all-powerful"; nevertheless, this seems to have been exaggerated in the translations into Latin. It may also be held that the concept cannot be understood in a literal fashion. For example, God cannot be expected to do what is logically impossible, like undoing what He is at the same time doing.

However, there are two common lines of defense whereby God's omnipotence is restricted. According to the first, it may be held that although God is certainly omnipotent, this only holds good for His part of the world. There is also an evil power, Satan, competing for world-wide power. This paves the way for an answer to the problem of evil, certainly the most common in popular discussions. The presence of this evil spirit has scriptural support and is the basis of the most common answer to the theodicy problem. If all evil is attributed to the presence of Satan, then God may be seen as wholly good, although not wholly powerful. This also makes place for the actions of human beings in the soul-making process. We are, so to say, asked to participate on God's side in the universal combat between good and evil.

Attractive as this line of defense may seem, there are some serious drawbacks to take into account. To begin with, we are faced with uncertainties concerning *how* strong this evil power might be. If strong enough, he may have won the game already, and this universe may be his playground. Or he may prove to be the winner in

the end, and therefore, we would do wisely by taking sides with him. Furthermore, and more seriously, this line of defense evades the original problem by creating a new one. If God is the original Creator of the world, then it seems that Satan could only be introduced into the world through immoral negligence by God or through evil intent by God. Either way, God is responsible for the evil brought by through Satan in the same way an instigator of a crime is held responsible for the deeds physically performed by those paid by him. So the Satan hypothesis eventually fails as a solution to the problem of evil.

The second restriction relating to the almightiness of God concerns the power given to man to act freely. If God has all power in His hands, then there seems to be no room for blaming His creatures for the evil acts they perform. They cannot be blamed more for what is going on than puppets that skip and jump with every tug of the strings held by the puppeteer. In accordance with this, premise (A) cannot be construed in a way that gives room for independent actions of man. However, the reasonable way to interpret (A) is that God has the (dispositional) power to do anything, although He does not necessarily have to act thus in every single instance, should He choose to avoid doing so. In this way, people may be held responsible for at least some of the evil in the world, as is claimed in some of the arguments that follow.

Although over the years, it has become more common to stress the goodness of God, some apologists (i.e., theists or lay people defending a certain creed) have claimed that it is far more important that God is almighty than that He is wholly benevolent, the reason being that we can only trust in God if He has the power to enforce His will. (This is the view of C. S. Lewis and P. T. Geach.) Others have objected to this on the ground that it is morally offensive to worship a being about whom one has serious moral objections. As put by H. J. McCloskey, "To worship, revere, adore, and to yield our wills to a being who may do evil or permit evil which we ourselves should feel morally obliged to prevent if we could, is to act in a morally irresponsible way, it is to abandon our moral autonomy in favour of a being we know to be capable of immoral acts."

This suggests that we would do better to examine the second premise and see if it is possible to modify it in a way that is consistent with moral and theistic beliefs.

Responses Concerning the Benevolence of God

To begin with, we may ask if it is necessary to think of God as wholly benevolent. What does it mean to claim that God is good? Since God is totally different from all that is known of earthly beings, what can be meant by addressing Him as good? Is not His goodness completely different from ours?

The argument implied by these questions, however, should not be stressed too hard as it could prove to be counterproductive for the theist. If God's goodness is *completely* different than ours, it may be objected that it may not be goodness at all. A skeptic (i.e., an interlocutor interested in questioning parts of some creed or other) may even add that, from what can be deduced from the world, it would be more feasible to claim that the Upholder of it all has a more relaxed moral standard than the one expected from God. If the apologist would claim that this judgment is dubious due to our shortcomings as moral beings, then it could be objected that moral judgments always stem from *our* moral beliefs, however defective these might be. We blame those who hold much power, e.g., presidents and dictators, not according to *their* standards but according to ours; and these are the same standards we use when blaming celestial beings. If we are asked to use a completely different moral standard when praising or blaming God, then we may rightfully ask if this is a moral standard at all. Furthermore, if we cannot understand the standard involved when it comes to God, this may also pose a problem since what we are examining is the moral goodness of God; in order to do so, we simply have to rely on our own standards, however imperfect these may be.

There is a better solution to take into account. God may, as claimed by Leibniz, actually have created the best world possible. Hence, He should

not be blamed but praised. There are several ways this argument could be developed. The first line of defense concerns the natural evils. Those who deny that natural evils are really evil, since their occurrence serves a greater good, usually claim that natural evil is part of a whole that is better than a whole without it. Therefore, suffering is not “really” an evil; it should rather be considered as a necessary means for a good end.

One way to do so would be to put it into a Darwinian frame. According to some ethologists, e.g., M. S. Dawkins, pain is the most expedient way to warn sentient beings from behavior that may prove dangerous for individuals as well as for species; hence, it can be shown to have evolutionary value. Therefore, pain can be explained as a necessary means for a world containing more evolved animals, and this is the kind of universe that God is expected to create.

Still, this does not wholly save the Creator from the accusation that the proceedings of the world are, at least in some instances, needlessly dependent on evil. There seems no good explanation to why toothaches should be so immoderately painful. Further, as claimed by the ethologist Richard Dawkins, the way that some animals are construed to interact in biotopes, for example, certain species of antelopes and some types of predators, seems to make the concept of a wholly good creator questionable. Surely, a wholly good and powerful being could have created a better system than this, e.g., by substituting pain with the diminution of pleasure, as suggested by David Hume. As it is, the idea that God should have created a system with animals designed to avoid the claws and teeth of others seems to make the premise (B) questionable.

Still, the debate could continue on this line. It could be claimed that natural evil is a necessary means, not only in order to make a first-order good (survival) necessary but also in order for making a secondary good (e.g., empathy) possible. It could be claimed that natural evil is a necessary means for making sympathy and other morally useful properties possible. Without pain, no empathy; and since a world where people act from empathy is better than a world totally

devoid of such moral properties, God would be expected to create such a world.

The skeptic may reply by pointing to the enormous amount of suffering in the world and ask if all this is necessary for bringing about these allegedly good properties. Surely, this is a clear case of overkill. And, further, he may add that the result of first-order evil is not only second-order good; we also get second-order evil, i.e., moral evil. Some people even seem to enjoy the atrocities that afflict others. There certainly is no lack of moral evil such as malevolence, cynicism, and cruelty in this world. Surely, this needs to be explained.

The apologist can retort that natural evil and moral evil serve a further cause. Without evil, how would one *know* that what is good is really good? This, the theist would claim, is no more possible than that a man who had never seen a shadow could really know what light is. However, the skeptic can respond that it is possible to *experience* good without any suffering even if suffering is necessary in order to *know* that one is experiencing good. Hence, moral evil still needs to be explained. One theistic way to do so is to claim that knowledge of the dichotomy between good and bad is needed, not only in order to really comprehend what is good but also for the gratitude that God expects from his followers. To this, the skeptic might retort that it is cynical to create this amount of suffering in order to get subservient beings to bow their heads to their Maker.

A second line of defense is to stress that the choice between moral good and evil serves a good cause, i.e., the soul-making process that makes human beings autonomous individuals who are responsible for their deeds and freely turn to God and as a result are rewarded with His friendship in the eternal afterlife. This is the famous *free-will defense*. The upshot of this is that there are some evils that may be engulfed by greater goods; some bad things may be seen as necessary means for a better general state of affairs than otherwise would be possible. For example, it may be held that a world containing pain is better than a world without it since pain makes compassion possible, and a world

containing compassion is better than a world without it. Further, a world containing certain types of moral evil, for example, malice, is claimed to be better than a world without it due to the fact that this makes possible the choice between good and bad acts; hence, in such a world, human beings cannot only feel compassion but also act morally. This capacity is not possible without free will. The utilizing of free will, however, often results in suffering as a bad but necessary consequence of the larger good consisting of this very capacity. Therefore, God is not only morally permitted to allow suffering and malice in the world, He is even morally *required* to do so since the good things that are added through this process makes the world better than it would otherwise have been. No less would be expected by a wholly benevolent being.

This is a strong line of defense, but far from conclusive. To begin with, it may be objected that the presence of moral goodness and the addition of free will in some agents hardly make up for the enormous amounts of suffering in nature. One may be forgiven to ask how antelopes and sheep are compensated for the suffering they endure by the addition of free will in one species that made its entry into the world very late in the evolutionary process. Secondly, the free-will defense is not wholly convincing even on its own terms. As the philosopher Anthony Flew once put it (in the atheist phase of his career), it is certainly possible for an almighty being to create a world where people freely choose only among good things. That is, God could have chosen to create beings “who would act freely but always do right” (Mackie). This is not, as some apologists have claimed, to use people as puppets and predetermine their behavior; as pointed out by Flew, “there is no contradiction involved in saying that a particular action or choice was: *both* free, and could have been helped, and so on; *and* predictable, or even foreknown, and explicable in terms of caused causes.” Everyone can act in a good way now and then; some do it most of the time, and a few do it consistently. These agents act according to their character and so are determined by that, which, of course, does not make them less free than agents who act morally wrong

most of the time. For God to prevent immoral people to be born is simply to use the divine powers of choice in reproductive matters so that only beings that consistently would choose to act benevolently were allowed to see the light of day. Obviously, an omnipotent Being can do this (and this is in fact what He is held to have created with Paradise). Since God has not chosen this alternative, He cannot evade responsibility for the evil acts committed by men. Hence, according to the skeptic, He is not wholly good.

Still, there is a line of defense left for the theist, what could be called *The Actual Person Argument for the Existence of God*. The theist may claim that for all the skeptical acumen shown by the skeptic, what he asks of God is a world that not only excludes skeptics (as well as theists, of course); it is also a world in which human beings as they are now would not exist. Not even the most convinced atheist would prefer a world where evil is totally absent. If placed in such a world, not only would the atheist be bored, he would also be stripped of the moral properties which make him the person he is. In a world completely devoid of evil, there would be no crooks but also no heroes, no moral goals to fight for, and no Dostoevsky novels. Certainly, it could be claimed, this is a worse condition than the present one. Therefore, God is not only permitted to create the world as it is, He should also be praised for it.

This may appeal to some atheists, but it is nevertheless not totally convincing. To begin with, it may be said on behalf of those more primitive creatures that suffer attacks by sharp-clawed animals, that the costs of this alleviation of human boredom are too high. And secondly, it can hardly be denied that the amount of suffering in the world outweighs the benefits in this process. Those billions and billions of animals that have suffered before human beings appeared on Earth seem, in this light, to have suffered in vain.

Further Lines of Defense

When presented with arguments like these, some theists take refuge in the inscrutability of

God. Some add that it is even sacrilege to present arguments like these, that it is wrong to question the supreme wisdom of a Being immensely more developed than we are. This, though it may perhaps dampen the questioning spirit of some believers, is of little help to the agnostic and will not silence the skeptic. To begin with, it could be claimed that we have to act on the rational and moral capabilities we are endowed with. Although limited, we cannot just hand over to authorities the problems that we must confront as moral beings, no less in a case like this than when we choose allegiance to political leaders. It could even be said that this is a further ramification to the theodicy complex. Why could not God have made us less susceptible to temptation, less inclined to doubts, especially when the price we have to pay is so high – eternal damnation, or at least exclusion from Paradise?

John Hick presents an answer to this problem. He claims that life on Earth, with all its suffering and insecurity, is a “soul-making process” whereby human beings mature to be friends of God. As in all close relationships, loyalty is tested, and as a result of faithfulness, the relationship is strengthened. Those who cling to faith even when much tells against it prove themselves especially worthy to be inhabitants of the reign of God. In order to make this soul-making process possible, it is necessary that the earthly surroundings contain so many occurrences that speak against the existence of a good Creator that it poses a challenge even to the most devout. Hence, the enormous amount of unexplained evil found in the history of mankind and other animals is necessary; it serves the purpose of confronting human beings with an objection that really works as a test of their faith.

How do we know if this answer is feasible? This, according to Hick, we will come to know when we knock on Heaven’s door. Viewed as a life strategy, this is judged differently by the believer and the skeptic (partly as a result of different conceptions of belief). For the believer, this can be held as a declaration of the hope inherent in belief. For the skeptic, whose conceptions are usually determined by scientific

demands of justification (rules of probability, etc.), it would be viewed as a kind of “intellectual Russian roulette,” similar to Pascal’s wager or the route to faith presented by William James in his essay “The Will to Believe.” Nevertheless, it is consistent with Christian teachings and may constitute an answer that works for the believer, although it does very little for the searching agnostic. As is the case with Dostoevsky’s *The Brothers Karamazov*, where Ivan’s skeptic objections are met by a kiss from his deeply religious brother Alyosha, the most powerful answer from the believer lies in the continuation of belief in the face of such strong arguments and so many daily examples of human cruelty and stupidity. The skeptic may conclude that he has shown not only that God is not worthy of worship, or even that there *cannot be* a God in the way the theist defines God (since at least one of the defining characteristics will have to go), but also that it may prove morally pernicious to worship a Being with so many ethical shortcomings. He may even hold, like Christopher Hitchens and other skeptics, that the belief in God has brought much evil to the world, e.g., the Crusades and the Inquisition. Still, the believer may hold that without a God, the world would be a much worse place, with no hope for those who are placed in the worst conditions and little consolation to all who are deprived of a close relative or of a sustainable life goal.

Evoked and Event-Related Potentials

Alberto Zani

Institute of Molecular Bioimaging and Physiology at Research Area 3 Milan (ARM3), National Research Council (CNR), Milan, Italy

Related Terms

[Averaged evoked potentials](#); [Electrical potentials](#); [Electrophysiological responses](#); [Evoked responses of the brain](#); [Scalp-recorded potentials](#); [Sensory evoked potentials](#)

Description

Evoked potentials (EPs) are small voltage fluctuations in the ongoing ► [electroencephalogram](#) (EEG) elicited by, and time-locked to, repeated occurrences of specific sensory, motor, or cognitive stimulus events. To extract average waveforms (also known as average “evoked potentials” of the brain) from the ► [EEG](#), it is necessary to sum and average the results of multiple trials. EP morphology varies as a function of the sensory modality (which are a type of nerves and centers that carry stimuli from sense organs (or receptors) to the central nervous

system and analyze their meaning. Different sensory modalities exist: visual, auditory, somatosensory, olfactory, etc.) of a physical stimulus; visual EPs (VEPs) are quite different from auditory (AEPs) and somatosensory (SEPs) EPs. In addition, amplitude (magnitude of the evoked potential, usually recorded in micro V or mV (one millionth of a Volt), with respect to a baseline computed on the basis of EEG signal amplitude over a time span of choice, usually 100 milliseconds, or ms, preceding stimulus event presentation), and latency (for example, the time between a flash of light and the major positive response in the occipital EEG, namely, P1), vary with the intensity and subjective relevance of events. EPs have been extensively used in human studies and have made important contributions to our understanding of neural systems that respond selectively to different types of stimuli in different sensory modalities and in the mapping of cortical and subcortical regions of the brain (Regan 1989; Barber et al. 1999). To date, these studies have successfully identified a set of robust potentials, named ► [event-related potentials](#), associated with several motor-cognitive-affective functions. The intracerebral sources of these potentials are also known to some degree (Donchin 1984; Zani and Proverbio 2003). Event-related potentials are a set of standard and robust electrophysiological potentials, abbreviated as ERPs, reflecting “higher-order” brain processing invoked in relation to mentations such as memory, expectation, attention, or changes in the mental state, rather than simply evoked by the physical impingement of external stimuli.

Self-Identification

Science

Since it was first introduced by GD Dawson (1951), the study of EPs has been pursued extensively and systematically, and much effort has been devoted to it by scientists from different fields including physics, electrophysiology, neuroscience, psychology, etc. EPs have always been regarded as valuable indices of brain sensory and

cognitive-affective functions. Historically, when there was an almost complete lack of noninvasive and harmless neurophysiological techniques for human research, EPs were considered the technique of choice for such studies. Since EPs consist of peaks and troughs, the polarity of which is indicated by the letters *P* and *N*, respectively, followed by numbers that denote their chronological order (e.g., P1, N1, P2), they provide millisecond-by-millisecond high-temporal resolution of neural processing (i.e., a measure of the ability to distinguish between two temporally close but not identical samples of the property being measured; it is expressed as the difference in values of a property necessary to make such a distinction, also called resolving power. EPs and EFs have a resolving power in the order of 1 ms or less). Earlier latency (<150 ms) peaks and troughs mostly reflect the activity of brain sensory areas (visual-occipital, auditory-temporal, etc.). Later-latency potentials, termed ► [event-related potentials](#) or ERPs, mostly reflect higher-order mind processes such as, for instance, attention, memory, and language. This is highly relevant to the unveiling of “online” sequential and parallel activation of different areas and systems of the brain during mental functions. Unlike any other modern ► [neuroimaging technologies](#), EPs/EFs are uniquely endowed with this valuable high-temporal advantage (Donchin 1984; Zani and Proverbio 2003). They have nevertheless suffered the limitation of a raw spatial resolution, a measure of the ability to distinguish between two spatially close but not identical samples of the property being measured, arising from the so-called inverse problem, namely, the problem of determining which sets of generators inside the head might have produced the EPs recorded from outside the head (Scherg 1992; Zani and Proverbio 2003). The devising of source analysis algorithms has allowed this limitation to be circumvented. Indeed, these algorithms, for example, BESA (Scherg 1992) and/or LORETA (Pascual-Marqui et al. 1994), make it possible to determine the intracranial generators of these scalp-recorded potentials (wave or voltage), in humans, without the need for parallel surface

(whether from the cortex or the scalp) and deep intracerebral recordings, as were usually obtained from nonhuman animals before ethical rules were established to prevent them. BESA or Brain Electrical Source Analysis; is a computerized algorithm for source imaging and electromagnetic dipole localization for EP and EF in research and clinical settings. Loreta is the acronym of low resolution brain electromagnetic tomography. Given measurements of scalp electric potentials and/or magnetic fields, this algorithm computes the exact 3D intracranial location (s) of maximal activity with a minimum degree of “blurring.”

Characteristics

Unlike other modern ► [neuroimaging technologies](#) for investigating human mind and brain functions, only EPs/ERPs and their magnetic counterparts (evoked fields, or EFs/ERFs), can, at present, contribute to elucidating the millisecond-based temporal progression of neural processing observed in the brain, thus increasing our knowledge of the dynamic functional interconnectivity across brain systems (Lehmann and Callaway 1979; Donchin 1984; Regan 1989; Barber et al. 1999; Zani and Proverbio 2003).

Relevance to Science and Religion

The major temporal advantage of EPs makes this subdiscipline/technique aware of its value in adding precise timing to the activation of brain regions identified by techniques with high spatial resolution but poor temporal resolution, such as PET and ► [fMRI](#). Currently, this makes the combined recording of electrical and hemodynamic signals in the same session the most advanced procedure in neuroscience for thoroughly enhancing our knowledge of where in brain space, and when in time, specific regions are active during a function, as in memory and attention processing (Donchin 1984; Zani and Proverbio 2003).

Sources of Authority

There are innumerable sources of authority for this subdiscipline/technique. These are not only eminent scientists from a range of domains from neuroscience to physics, including, mathematics and electronic engineering, but also milestone papers, books, and dedicated journals. These sources are authoritative because they have devised new theoretical viewpoints or introduced new methods of analysis, as well as identified previously undetected potentials associated with individual sensory and cognitive processes, thus boosting the power of EPs/ERPs to address hard questions such as “What do these potentials indicate?” during brain processing, or, from a more general view, “Where do they come from in the brain?”, as well as “How do the brain and mind work?” Overall, then, the strength of the linkage of these potentials to cognitive neuroscience undertakings has been increased. A great deal of time and space would be required to review all these sources; in view of the limitations, only a very few selected ones will be considered here.

In 1964, Kornhuber and Deeke found a scalp-recorded electrical reflection of motor cortex activity leading to voluntary muscle movement, which they called *Bereitschaftspotential* or BP and was later known as readiness potential because of its relationship to the pre-motor planning of volitional movement (Kornhuber and Deecke 1980). In two related studies in 1965, Salomon Sutton and colleagues found an enhanced positivity with a latency apparently ranging from 200 to 300 ms related to “stimulus uncertainty,” while in 1968 and 1969, Walter Ritter and Vaughan found a similar positivity in conditions related to “stimulus novelty,” later known as the *P300*. Thereafter, Emmanuel Donchin and his students (Donchin and Lindley 1969; Donchin 1984) at the University of Illinois brought the study and interpretation of the functional significance of the *P300* potential for evaluating cognitive information to unprecedentedly high levels. During the 1970s, Risto Näätänen and his group (Näätänen et al. 1987) at Helsinki

University recorded a so-called mismatch negativity, or MMN, 150–200 ms after occasional physically deviant auditory stimuli in a stream of otherwise identical stimuli. This MMN is elicited by deviations in any auditory feature and increases as the feature becomes more deviant. In 1980, Marta Kutas and Steven Hillyard at U.C. San Diego pioneered studies of the response of language areas to semantic stimuli, recording a so-called N400 after presenting an incongruous word in sentences such as “I like pizza with mozzarella cheese and *nails*.” Overall, these potentials, or components, have provided a specific taxonomy of EPs/ERPs that has subsequently been widely used in numerous research and clinical settings (Kutas and Hillyard 1980). The untimely death of Russel M. Harter in 1990 should not go unnoticed; he was at the peak of his career, after having contributed much during the 1970s and 1980s at the University of North Carolina at Greensboro to identifying the neural substrates of human visual perceptual development, pioneering the recording of infant VEPs. Last but not least, we must recognize the outstanding work of Terence W. Picton (Picton et al. 2000), Michael Scherg (1992), Paul L. Nunez, F.H. Lopes da Silva, H. Spekreijse, Roberto D. Pascual-Marqui (Pascual-Marqui et al. 1994), D. Lehmann (Lehmann and Callaway 1979), D. Regan (1989), and many other leading scientists not mentioned here for space reasons who made important contributions to establishing methods for locating the sources within the brain of potentials recorded from the surface of the scalp. Since 1949, the “Electroencephalography and Clinical Neurophysiology” Journal, also known as EEG Journal, comprising the “Electromyography and Motor Control” and “Evoked Potentials” subsections, has also been of great importance for fostering research and disseminating information in this field. This journal has always been, and remains, the official organ of the International Federation of Societies for EEG and Clinical Neurophysiology. For this reason, its name was changed to “Clinical Neurophysiology” in 1999.

Ethical Principles

In line with the Declaration of Helsinki in 1971, clinical, diagnostic, and research activities performed in the context of this subdiscipline/practice are guided by sound ethical principles of patient/subject care and interpersonal and communication skills, as well as by standard guidelines for psychophysiological research, compiled by a panel of outstanding scientists in this field (Picton et al. 2000).

Key Values

The key values of this subdiscipline/practice are to use information technology to appraise and assimilate evidence from scientific studies to enhance patient care outcomes in clinical settings, and to enhance our knowledge of the functional activity of brain sensory, cognitive, and affective systems.

Conceptualization

Nature/World

Nature, in the sense of the natural or physical world, is seen to represent all the physical stimuli eliciting a functional or dysfunctional bioelectrical response in the brain, no matter whether or not the latter is consciously aware of them.

Human Being

The human is seen as a complex biological system in which both lower-order sensory and higher-order cognitive brain processes may be studied, the latter seen in nonhuman animals to a much lower degree.

Life and Death

Life is defined as a state of brain responsiveness to the external world as indicated by the presence of EPs, no matter whether individuals are aware of and consciously report the events that elicit them. EPs are therefore objective signs of life in individuals in a coma, where there is still some sparing of cortically based cognitive brain

functions besides subcortically regulated visceral ones such as the cardiac cycle and respiration. Conversely, death is usually considered as the absence of such brain potentials due to the irreversible cessation of all the forebrain and brainstem functions, even in conditions in which the heart and lungs are still working, thanks to the action of ER equipment (Lehmann and Callaway 1979; Donchin 1984; Regan 1989; Zani and Proverbio 2003).

Reality

Reality is a contentious term that, in its widest sense, might include everything, that is, whether or not it is observable or comprehensible. In a most general way, EPs reflect brain processing related to everything, that is, mostly at the physical sensory level, independent of awareness, which is related to higher-order processing or cognitive levels in the brain and thus to the activity of the so-called association cortices. To some degree, this higher-order activity is reflected in the ERPs (Donchin 1984; Zani and Proverbio 2003).

Knowledge

Knowledge is rationalized in terms of neural processes that link stimuli to successful behavior in complex and challenging environments. These processes are referred to as the way humans and nonhuman animals acquire, manipulate, and use information in the context of mental functions. EPs have contributed successfully in reflecting the neural mechanisms underlying all these functions by means of appropriate experimental setups, in which the patient/participant performs tasks, and stimuli differing in meaningfulness are administered to “probe” the underlying neural electrical activity thus elicited.

Truth

EPs may serve as “clues,” on the one hand, to the impingement of events in the external and internal physical world on brain systems, irrespective of their conscious experience, and on the other, to their mental representations, irrespective of their “true” presence. Indeed, robust evidence has been obtained of EPs/ERPs recorded in conditions in

which no stimuli were actually presented because they were “omitted” in a sequence, elicited simply by strong subjective expectations (Donchin 1984; Zani and Proverbio 2003).

Perception

Perception is thought of as an active construction process, and a form of conscious awareness of the objects of the external world that transcends the simple sensory processing carried out by the primary and secondary cortices, notwithstanding the importance of this basic processing for analyzing the features of physical stimuli and objects. EPs have provided meaningful knowledge of the sensory and perceptual processes of the brain for the major sensory modalities (Donchin 1984; Regan 1989; Zani and Proverbio 2003). For instance, a relatively early latency P100, or P1, recorded from the occipital scalp, changes in amplitude as a function of check size to produce an inverted U function, the low amplitude values of which are associated with both lower and higher check sizes, and the highest amplitudes with medium sizes of 10–15 min of arc. However, for active perception, active involvement of the frontal and parietal association cortices is also thought to be mandatory. As a proof, neurological patients with a lesion in the right inferior parietal lobe (causing a hemispatial neglect syndrome), but intact occipital lobes, show a normal P100 at the right occipital scalp in response to patterned visual stimulation from the left visual field, contralateral to the side of the lesion, but do not consciously perceive these stimuli. Conversely, patients with a lesion in the visual occipital cortex (blindsight patients) cannot see stimuli from the external world and show no P100 at the scalp over the occipital cortex. Overall, these EP findings reflect normal visual sensory processing, but impaired perceptual conscious processing, in the neglect patients, and impairment of both sensory and perceptual processes in blindsight patients.

Time

Time has a very special meaning for EPs. Unlike other timescales, in the order of nanoseconds, seconds, minutes, or hours/days, proper to

subcellular, cellular, and whole-system structural and functional brain functions, the millisecond-based scale used to measure the time of appearance, or latency, of the various peaks and troughs in the EPs/ERPs, indicates the stages of neural processing that an external or internal event undergoes in the brain, closely paralleling “online” the actual timing of mental and behavioral functions (Donchin 1984; Regan 1989; Zani and Proverbio 2003).

Consciousness

Consciousness is a complex concept that includes neural processes relative to the state of wakefulness, awareness of the world and the self as an actor in the world. Most of these neural processes occur at an unconscious or automatic level. The relationships of EPs and ► EEG signals to consciousness differ markedly. Indeed, EEG simply provides a generic index of individuals’ wakefulness, or arousal, ranging from coma to alert wakefulness. Conversely, EPs can provide a measure of the time-locked and selective responsiveness of the brain to sensory and cognitive events as a function of the subjective relevance of events. To some degree, this makes them possible signs of some of the neural processes strictly related to, or preceding, the conscious mental processes elicited by these events (Donchin 1984; Zani and Proverbio 2003), some in particular; for instance, the so-called N400, a wave recorded about 400 ms after the occurrence of a linguistic stimulus, such as the word “sock” presented at the end of a sentence such as “I like my roll with mustard and sock.” This wave, then, seems to reflect brain processes related to the subjective realization that this word is semantically odd with respect to subjective expectation – for instance, “a hot dog” – and/or to the successive conscious mentations elicited by this realization (Kutas and Hillyard 1980).

Rationality/Reason

Traditionally, rationality has been regarded as that which is rational and capable of sound and goal-directed reasoning for problem solving and decision making, following given rules or otherwise, as opposed to being irrational or incapable

of reasoning. There is considerable evidence that psychiatric populations with altered reasoning ability and mental faculties show alterations in both EPs/EFs and event-related potential morphology (Regan 1989; Barber et al. 1999; Zani and Proverbio 2003).

Mystery

EPs may provide insight into the mystery of brain functioning in terms of time-based parallel and sequential functional inter-activations of its manifold ► [functional systems](#).

Relevant Themes

Some additional issues are especially relevant to this subdiscipline/technique, as to any other life science disciplines, from the “Science and Religion” viewpoint, issues that have been considered by many thinkers throughout human history. If, from a religious point of view, the mind stemming from the brain is to be strictly considered as arising from a spiritual soul, should the absence of brain responsiveness – as reflected by the absence, after death, of any evoked potentials – be taken to indicate that this spiritual entity has been separated from its material “reservoirs,” the brain and body, now incapable of any response per se? If so, a “dualistic” view of soul/mind and body, or, in more up-to-date terms, mind and brain interrelationships, should be maintained. However, many accomplishments of neuroscience currently support a “monistic” view of mind and brain, as dependent on biological processes and independent of the spiritual soul. This has made, and will continue to make, these issues the subject of intense argument (Donchin 1984; Zani and Proverbio 2003).

Darwinism

In a general sense, evolution is one of two different kinds of change, the other being development. Based on the usages in biology, where both kinds of change are studied, development can be defined as “predictable directional change,” and would be a constitutive aspect of any dynamical system, as seen, for example, in the developmental stages of an embryo, which go through a predictable sequence. At a simpler level, tornadoes also go through predictable stages of development. Evolution, on the other hand, would be the “irreversible accumulation of modifications and marks” resulting from encounters with other systems or forces. It produces individuation. Such marks can form a record of historical changes. A simple example would be the craters on the moon. A more interesting example would be changes that occur as a result of mutations in the DNA information storage in the cells of organisms. Such mutations are known to mark some of the changes that have occurred during biological evolution. All natural systems both develop and evolve (individuate). They develop insofar as they are members of a class of dynamic things, and their characteristic changes are constitutive of their being in time. They also evolve/individuate because they inevitably get modified when they interact with other things and systems.

In its most general sense in science, “evolution” means progressive change. That is how physicists, chemists, astrophysicists, and sociologists use it. In these fields, it is usually taken to be predictable (hence “progressive”), as in the changes producing the main sequence of stars, or in the “evolution” of alcohol during fermentation. Biological evolution has been taken to be not predictable, largely because neo-Darwinian theory is based completely on chance occurrences, as explained below, and as emphasized so strenuously by Stephen Jay Gould, who wanted to rule out all notions of progress from biological evolution.

Science has for the most part been involved only with development, leaving evolutionary changes as the province of history. Philosopher of science Karl Popper spoke of “the poverty of historicism,” referring to the fact that it is difficult to use history for pragmatic purposes. Only predictable changes can be modeled. There have been exceptions in science, such as historical geology and evolutionary biology. The technique of historical geology has been to take several different kinds of evidence from any given sequence in the geological record. Each kind of evidence can be used to corroborate (or not) what was found with other kinds of evidence taken from the same record. In this way, a geological time period can be “run through” over and over again, building up a coherent picture from different lines of evidence. This is analogous to checking to see if some developmental event in an embryo is repeated in other embryos, where other embryos are used to supply evidence for each kind of experimental probe. So history can be studied by science if preserved traces can be studied by many different techniques, as can be done with the fossil record. Based on studies by paleontologists of fossils and the strata they are preserved in, biological evolution has been constructed as an inferred process of replacement of kinds of living systems with others over long periods of time on the earth. The fossils have been located in time by historical geologists using physical techniques for dating the enveloping rock strata.

This record gives us an idea of the sequence of living beings that inhabited the earth.

The idea of biological evolution is founded upon the inference that earlier living forms gave rise to later ones in a kinship relationship based on reproduction. Indirect methods of finding relationships between living beings are comparative anatomy, which Darwin and his forerunners used to imagine biological evolution in the first place, and comparative genomics, which is now the major tool for establishing kinship relationships between kinds of living things. The conceptual model used in these studies is what Darwin called “descent with modification.” Here, greater similarity is taken to reflect closer kinship, and processes of change are held to result in accumulating differences as time passes from generation to generation. So the model is one of ever-increasing difference from original ancestral forms as generations succeed each other over time. During this process, driven by reproduction, new species occasionally come into being if the accrued changes prevent interbreeding with populations of the older kinds. This process of descent can be modeled overall as a tree, with the oldest ancestor in the trunk, and with new branches marking the origin of new species. One result of this process would be to increase the number of different kinds of living things, as well as the number of different kinds of environments they live in as they migrate to unoccupied regions. One would also expect an increase in the number of resulting ecological relationships among the different kinds. So this model of “descent” explains the variety and disparity of living things.

Concurrently, we have also found in the evolutionary record a process of increasing complexity in the newer kinds of living beings appearing later in the record of evolutionary change. The earliest living things were simple masses of single cells, each reproducing separately. To these were added multicellular kinds of different sorts on different branches of the “tree” of life (e.g., sponges, plants, animals), and to these were added kinds that live in social systems, as well as kinds that engage in building things. As a result, we find that our descriptions of living beings

need to get increasingly more complicated as we describe kinds appearing more and more recently in the record. This pattern of change is not implied by the “descent with modification model,” which only predicts the generation of increasing numbers of kinds of living things. Since it is common for developmental processes to show an increase in complexity of a developing system (as in the egg to chicken sequence), it has been suggested that biological evolution might also be a predictable process for any planet with moderate enough conditions that could support life. That is, there is some evidence that biological evolution can be considered to be an aspect of a large-scale developmental process of the surface of any earth-like planets. Any developmental process always involves individuation of the developing system as well, because historical accidents are always occurring in any material system. Therefore, development is always evolutionary in part. Biological evolution, then, would be “evolutionary” in its creation of many new kinds, and may also show a developmental tendency in its creation of increasingly complex kinds of living beings as it continues over time.

The above statements make up what can be called the facts of biological evolution – dated fossils and graded series of increasingly dissimilar anatomical resemblances accompanied by increasing degrees of genetic difference. Some religiously motivated persons may refer to this body of information as “the theory of evolution,” which might better be stated as “the theory that evolution has occurred.” However, what is described above is not taken to be a theory in the usual sense (involving causes) at all, but a logical inference based upon facts from several sciences, ranging from physics, through chemistry and biology, to anthropology.

There actually is a theory of evolution that informs the thinking of evolutionary biologists, and this is the “neo-Darwinian theory” – the theory that evolution is mediated by natural selection. This theory, along with several others as well, was sketched out by Darwin, and has been developed by subsequent evolutionary biologists as a largely mathematical theory of

population genetics. It concerns how some genetic predispositions can replace others over several generations in a lineage of populations. It is a theory of competition between genotypes (which code for phenotypes like the brown eyes/blue eyes alternatives in people) for relative representation in the next generation. Genotypes that reproduce most successfully would gradually replace competing types, and are then said to be the more “fit.” It is assumed that this differential reproduction (with the best said to have higher fitness) is usually a sign of better adaptedness to existing environmental conditions. Fitness involves two components – viability and fertility – which make up the phenotype of a kind of organism. Viability refers to the ability to make a living and to survive the various hazards facing living things, while fertility refers to the ability to attract mates and successfully produce and (in some cases) raise offspring. A genotype’s fitness is measured as the number of surviving offspring of that type in the next generation relative to most successfully reproducing genotype.

The neo-Darwinian theory has built into it an important provision that relates closely to the controversy between religion and biology. This provision is now coming to be increasingly criticized within evolutionary biology itself as not only not being required, but as not being even a plausible restriction. This important provision is that *new forms and behaviors can appear in organisms only by way of random mutations of genetic predispositions*. “Random” here means “random with respect to the needs of the organisms.” This provision forestalls the possibility that there might be some agency, like a deity or other as-yet-undefined factors, influencing evolution, since the changes that might increase fitness are held to necessarily occur prior to the possibility of their becoming useful. This basic assumption is a purely ideological constraint on the neo-Darwinian theory, and restriction to it has no basis in observation. Some evolutionary biologists are now interested in the idea that organisms themselves might influence new forms by way of changing behavioral patterns or by changing the hormonal environment of their cells, which is where the deployment of genetic information

takes place. It is now clear that regulation of genetic information is more important than changes in that information in generating new phenotypes, and such regulation could plausibly be influenced by the biological system itself.

Possible influences by a living system itself on what new phenotypes may appear during evolution are coming to be assimilated under the label “self-organization.” This change in perspective allows organisms themselves to have a role in upcoming evolutionary changes. In the neo-Darwinian theory, there can be no effect of organismic intentionality upon evolution; they (and we) are viewed as mere hapless pawns in the competition between genotypes in a population. Some neo-Darwinians have even proposed that genes are the agents in evolution, with organisms being relegated to being mere “gene machines,” or “vehicles” for the promotion of genetic varieties. So the enforced randomness of gene mutation, installed in the neo-Darwinian theory in order to eliminate the possibility of *external influence* upon evolution, is being challenged instead by the possibility of *internal agentive action* by living beings themselves, as suggested by some studies in the field “Evo-Devo” (Evolutionary Developmental biology). This invokes unease among many scientists because Western science has been wedded to the idea that all of Nature works mechanically, with no influence of desire. This is why Francis Bacon excluded Aristotle’s final cause from consideration in science. Natural selection only eliminates the relatively unfit, and creates nothing new. It is strictly a negative “weeding out” process, revealing success in reproduction subsequent to changes being made by self-organization. It can now be said that *natural selection (selection by consequences) only disposes what self-organization proposes*.

The neo-Darwinian population genetics theory has been embedded in a larger, more encompassing theoretical nexus, called the Synthetic Theory of Evolution. This was a hoped-for union of population genetics, natural history, paleontology, comparative anatomy, developmental biology, and animal behavior. It is interesting to note how fully the randomness idea has suffused this entire theoretical orientation

in biology. (1) The supposed randomness of mutation as a source of the new has already been noted. (2) The willy-nilly wanderings of animals, spores, and seeds has been cited as important in the establishment of new species because new populations might come by chance to be established far enough away from the source populations so as to interrupt interbreeding. A long period of evolutionary changes in separated populations after this would be enough to establish a new species after the accumulated genetic differences became great enough to have rendered the genomes incompatible in a hybrid. This “allopatric model” of speciation has been the dominant one in the Synthetic Theory. (3) In the population genetic theory, evolution is always characterized as being kicked off by environmental changes occurring without respect to the needs of the organisms in a population – that is, occurring at “random.” (4) Since biological populations of larger organisms are often rather small, there is commonly a statistical sampling error determining which genes might get passed on to the next generation, called “genetic drift.” This means that varieties that get subjected to selective culling are often chosen in advance by accidental events. (5) At a larger scale, unforeseeable “pre-adaptation” is supposed to have been a major mediation of new ways of life. For example, the fish-like ancestors of the first vertebrates to leave water for dry land appear to have already been walking in the shallow waters where they lived, and they were already breathing air in those stagnant tropical waters. We might note that some modern fishes do both. It needs always to be the case that, in order to get going in a new way of life, there must be some way of gaining a foothold – once again, the only alternative seems to be chance.

It is interesting to note that logically, there is no way to tell the difference between a chance event and an arbitrary action. Chance events are characterized when data about collections of some kind of event fall into frequency distributions that can be fit to some probability density function. But when a collection of instances of a type of deliberate, agentive action is subjected to statistical analysis, it too can be found to be “random.”

For example, the frequency of pairs of moves in master chess games, and of pairs of notes in a classical music score, can be shown to fit a Poisson distribution, even though they were obviously not made “by chance.” This makes an ironic footnote to the Synthetic Theory’s focus upon randomness. This bias would seem to be a veritable invitation for those who wish to imagine a supernatural hand in evolution to assert that all the seemingly random events were actually directed from outside by a deity. There can be no logical objection to that assertion, and so the difference of interpretation becomes merely an assertion of wills. For this reason alone, atheists will be inclined to accept the ideological change privileging self-organization instead of randomness in the generation of new departures in evolution.

We can explore further the relationship between natural selection and the evolution of changes in organisms over time, a process that has been labeled “macroevolution.” This label is poised in distinction to “microevolution,” which refers to the changes in gene frequencies from one generation to the next as resulting from natural selection. It was long assumed that microevolution repeated over thousands of generations would gradually add up to macroevolution. That was Darwin’s own view, and this “gradualism” was taken to be the norm for biological evolution until recently, when it was shown that phenotypic evolution often goes by spurts and jumps, sometimes in response to dramatic environmental change. Genetic change by way of selection over the generations would logically be gradualistic, but we see that organismic changes need not be. A further point is that any feature or function of an organism is influenced by many genes. The neo-Darwinian theory does encompass the evolution of many genes simultaneously (as modeled in the computation technique, “genetic algorithms”). Most biological functions involve more than one trait, and the simultaneous evolution of many such traits, insofar as they affect one function, can be dealt with successfully by neo-Darwinian theory. There remains, however, a conceptual problem with the simultaneous evolution of many independent functions, yet to be solved within selection theory.

Macroevolution can be explored further with a famous example used by religious objectors to evolution – the evolution of the eye. They point out that since an eye would not function unless all its features were in place, it seems impossible to imagine all of these getting gradually improved simultaneously because in the selection model, there needs to be functional superiority in each generation in order to propagate some variety of a feature. An “unfinished eye” could not have any selective advantage in respect to vision. As well, since each feature needs the others to collaborate together in order to produce vision, they could not evolve in tandem either. This example poses problems for the selection model; natural selection, selecting by consequences, cannot foresee future benefits. In the selection model, one is required to imagine improvement of all the future parts of the eye as occurring because each step was adaptively superior to other, competing forms, long before they came to function together as features of the eye. That is, each future feature of the eye must be viewed as having been involved in other functions that were selectively favored. There could have been no selection pressure favoring vision until just before the advent of the eye. For example, the pigment cells in the retina could have had light-sensitive ancestral cells that functioned merely as detectors of light and dark, without any image forming ability. Only in later generations of succeeding populations in descendent species would they get co-opted into the focusing eye, a process labeled “exaptation.” This is the formal Darwinian answer, but whether there is in fact a sequence of ancestral populations with adaptive pre-eye components actually known from the fossil record is questionable. Lacking such a record, evolutionary biologists can only believe that such a sequence must have occurred. The belief rests on plausibility. That is, as is frequently the case in science, there can be a logical in-principle solution to a problem before that solution can be demonstrated empirically.

Another important aspect of macroevolution that is problematic for neo-Darwinians – *convergent evolution* – is explored in a separate entry in this encyclopedia.

Concerning the ideological aspects of evolutionary biology, we might consider how a process that supposedly produced us could not have ideological implications. Science is not free from ideology, as Marxist scientists were insisting back in the 1880s of the nineteenth century. Long before that, the connection of Darwinism to Capitalist ideology was being formed, given the influence on Darwin’s thinking by texts like those of Malthus. Capitalism values the growth of competing firms, while Darwinism values the relative growths of different genotypes in a population. It was said that Darwin imported Capitalism into Nature when he formulated competition between different types in a population for reproductive hegemony as the basis of evolutionary change. Subsequently Social Darwinists justified their particularly brutal view of the human economic situation by appealing to its naturalness – Nature red in tooth and claw! More recently those neo-Darwinians known as Sociobiologists promoted similar views, which an even more recent group known as Evolutionary Psychologists have tried to ameliorate. They, however, still use the basic mechanism of reproductive competition between various types in a population as the motor of evolution, producing natural selection. And so, we who are here today would be seen to be the offspring of a series of ancestors who outcompeted (by successfully outreproducing) the ancestors of other possible folks who are not here instead! Competition is therefore the source of all good, based on a random – that is, pointless – production of competing genotypes. Insofar as it is insisted that nothing is directing the evolutionary process, and that it is not developing in any particular direction, it is without any intrinsic meaning. Gould was fond of noting that it was just pure accident that our lineage did not go extinct long ago, as most kinds of animals have.

It needs to be noted that there are today at least four groups that have an interest in shaping our culture’s creation myth (using “myth” in its ethnographic sense of an account of what we are, where we came from, and what we should be doing to reflect those origins.) There are, most prominently, the neo-Darwinian evolutionary

biologists, who feel that they, as scientists, ought to have exclusive rights to interpret organic evolution. There are, actively contesting them, religiously based Creationists (fundamentalists in all three of the Abrahamic Faith Religions would presumably have a stake in the Genesis story). Then there are, somewhat less prominent now, the Marxists, who object to the notion of genetic determinism that almost automatically follows from the neo-Darwinian idea that only genetic information can be passed on from one generation to the next, reflecting the properties of the winning genotypes in the reproductive competition. They promote instead the idea that Man can be molded by social arrangements regardless of inherited predispositions. Finally, there are the ideological Capitalists, for whom the valorizing of competitive production in our basic myth can only be a good thing.

So, we see that the large changes in phenotype over time that we call biological evolution, or macroevolution, has been established as an almost inescapable fact. At the same time, the dominant – indeed, the only current – theory of biological evolution, the still unfinished theory of natural selection, or microevolution, deals only with changes in the proportions of genetic varieties in a population over a few generations. It is a theory that depends upon accidental occurrences at all levels involved in evolution, from cells and organisms to populations and biological lineages.

[Biological evolution](#); [Evolution](#); [Organic evolution](#)

Ever since Darwin, and implicitly even before his work, the pattern of biological evolution has been viewed as one of “descent with modification” (Darwin 1859). That is, since biological evolution is mediated by changes occurring during the development of individuals and the reproduction of populations, there could be many different changes made to the common phenotype in a population in different instances and at different times. This will sometimes give rise to descendent lineages deriving from the original population as a result of animals, seeds, spores, or other propagules spreading out into new locales. Since the same principle would apply to all the newly

formed populations as well, we would have a resulting pattern of increasing numbers of biological lineages descending from an original population. This pattern can be visualized as a tree evolving from a common ancestral population represented in the trunk and with an increasing diversity of living things represented in the branch tips. Comparative genomic studies have corroborated this model by showing that genetic difference increases along with phenotypic (anatomical and behavioral) difference. That is, if we arrange living things on a conceptual tree, with increasingly different forms spread out into the branch tips, we find that genetic difference generally follows the same pattern.

So, given the fact that the genetic information, which informs the construction of the phenotype, parallels the apparent pattern of increasing diversity of living things during evolution, the principle of “descent” appears to be a sound model for evolution. Given this picture, it is natural to expect that the disparity among living things would be continually increasing during evolution as well, resulting in such different beings as, for example, sponges, butterflies, and fishes. If we look over all living things, this expectation does seem to be corroborated in general. However, upon closer examination we find more than a few puzzling cases where, even though the genetic difference might be great, phenotypic similarity is much greater than would be expected given that fact (Willey 1911; Conway Morris 2003; McGhee 2011). In taxonomy these cases of similarities between evidently distantly related kinds is called “homoplasy.”

Now, in some cases homoplasy is easy to understand as a result of the requirements of adaptation to a given environment. For example, fishes, porpoises, sharks, and fossil ichthyosaur reptiles all have very similar streamlined bodies that allow them to swim rapidly in the dense medium of water. General shapes like these can be coded for by at least partly different genetic information, allowing for many ways to solve an adaptive problem, mediated by natural selection. As well, it is easy enough to understand how closely related species might give rise to descendants that take up the same way of living

separately. This, called “parallel evolution,” can be seen to result from similar genetic and organizational predispositions and body forms being subjected to similar environmental selection pressures. An example is found in the several frog families that have independently given rise to species that lay their eggs on land instead of in water, or which come to brood their eggs inside the body of a parent. Certain possibilities would naturally be inherent in a given phenotypic organization informed by similar genetic predispositions. So, some cases of homoplasy are easily explained within the general Darwinian viewpoint, especially if they are similar only in a general sort of way rather than in detail.

However, there are many cases of homoplasy that cannot be readily understood using the Darwinian “descent with modification” perspective. In these examples, kinship relations are quite to very distant, and the similarities are surprisingly alike. These cannot be understood using the “descent” principle alone. Here are some examples:

1. Jellyfish, squids, and vertebrates have focusing eyes on the same plan. It is known that the clear protein that makes up the lens is coded for by different genes in these cases. The genes are different, but the form and function are the same. Amazingly, the same form is found as well in the eyespot of single-cell dinoflagellates.
2. Both old man’s beard (a lichen) and Spanish moss (a flowering plant) live as finely dissected grayish masses draped over the branches of trees in misty coastal environments, the first in northeastern North America, the second in southern coastal regions. They are organized so as to capture water from mist, and minerals from dust.
3. Both the very primitive hagfish in the oceans and an Amazonian catfish live by burrowing into large rotting corpses that have drifted into deep waters. Their bodies have converged upon a muscular eel shape covered in slime, which can tie itself into knots.
4. The primitive freshwater fish *Polyodon* and the basking shark have evolved the same body form, mouth structure, and behavior

for feeding upon microscopic plankton. It should be noted in this case that there are other kinds of body designs for this same economic activity, notably in the whale shark and among whalebone whales. That is, we cannot explain these similarities by claiming that there is only one possible way to achieve this particular way of life, in which case natural selection would have been sufficient to explain the similarities.

5. The New World vultures have evolved from storks, while Old World vultures evolved from hawks.
6. Hummingbirds and hummingbird moths have evolved the same body form, general size, and hovering behavior that allows them to feed upon nectar in flowers. Other birds and butterflies have achieved this economic activity in quite different ways.
7. Large complicated underground nests with tall chimneys for air conditioning have evolved both in some tropical ants, related to wasps, and in some tropical termites, related to cockroaches.
8. A stunning larger scale example is found in comparing the many body shapes and lifeways of marsupial (pouched) mammals with those of eutherian mammals (like us). The faunas of each, which evolved independently on separate continents, duplicate the same major forms and lifeways, like those of wolves, mice, and badgers – even saber tooth tigers. We do find a few very specialized kinds in each group that were not duplicated in the other fauna, like the eutherian bats. Also, while the lifeways of kangaroos compare closely with those of antelopes and deer, their body forms and progression are different, and so not all the ecological duplicates in this general example are as closely similar as most of them are.
9. An even larger scale example is found in the fossil record, when early paleoniscoid fishes were replaced, after a mass extinction, by holostean fishes, and when these were replaced after another large-scale extinction by modern teleost fishes. All of these faunas evolved the same panoply of body

forms – minnows, pikes, eels, flatfish, panfish, and so on. This pattern of replacement has been called “iterative evolution.” Again, there are some unique forms, like teleostean seahorses, not found in the earlier faunas.

10. Agriculture was evolved separately by humans, ants, termites, and bark beetles.
11. Another large-scale example is the evolution of similar vegetations in different regions, while the species are all different. A well-known example is the Mediterranean vegetation profile found also in the Andes Mountains, South Africa, California, and in Australia. In this case, the similarity clearly involves factors larger in scale than organisms.

We find an interesting example in comparing seahorses with chameleons. Both of these are slow moving, camouflaged stealth hunters using a very rapid strike at their prey. They move about using prehensile tails to grasp the vegetation they climb about in. Both have independently moving eyes. Seahorses have live birth, as do some chameleons. The extreme difference in habitat in this example, as well as the significant distance in kinship, magnifies the importance of these similarities. Note that the actual mechanism of prey capture in each case is quite different, with seahorses using a sucking action and chameleons using a long sticky tongue. This shows that, whatever the forces eliciting convergent similarities here, they cannot transcend historical differences that have accrued in the two lineages separately. This should serve to remind us that in evolutionary convergence similar forms evolve from very different ancestors.

This brings us to the question of what might be causing this widespread limitation in evolutionary possibilities, which, on the Darwinian “descent” model should be unlimited and should produce similarities only very rarely, by chance. Darwinians invoke chance, conditioned by similar selection pressures. The only other conceptual possibility raised so far that might work is the structural attractor idea from the field of dynamical systems. Structuralism has been an approach used in linguistics and in cultural anthropology, where again interesting similarities and

limitations are found. The idea generally is that there are structural attractors, or “deep structures” in nature that exert a pull upon phenomena resulting in their being reflected in many similar “surface structures.” In the case of biological evolution, there are as yet no candidates for “deep structures.” A far-fetched non-structuralist possibility from genetics might be imagined by way of the lateral transfer of genes carried by viral infection. It is also known that many genes are conserved during evolutionary changes, and so the same genetic information might be lying dormant in many lineages. But this would not explain why these genes would be brought into play in cases like the seahorse and chameleon. Possibly more interesting, it is known that gene regulation can manipulate the same genetic information to get different results, so why not imagine the possibility that gene regulation could turn different information to producing the same results? But, again, given that adaptation by natural selection can produce a variety of adaptations, why should it produce duplications? Somehow, these genetic possibilities do not seem very convincing as an explanation of evolutionary convergence, especially considering that convergence is found even at the ecological level, as in the Mediterranean vegetation patterns. In this case, fire has been at work, but why is there only one kind of response to fire? We know there is not just one response because in Australia there are other, non-Mediterranean-type fire disclimax biomes.

It might be noted that our logics make it very easy for us to see how differences can accrue in changing systems, but very difficult to imagine how similarities between different systems might arise. Any unplanned change is more likely to create a difference from what was present before the change. But it requires elaborate technologies in order to generate similar forms, as in a factory, or during organism reproduction, which is guided by the genetic system. Evolutionary biologists have simply put this problem aside, sometimes by suggesting that on the genetic level there is only parallel evolution (Gould 2002), if indeed, they acknowledge it at all (Pigliucci and Kaplan 2006).

Description

Evolutionary biology is a subdiscipline of biology, and of historical geology and physical anthropology. Recent advances have been in using DNA comparisons to determine the degrees of relatedness of various lineages of living systems, and in bringing in ontogeny (development, in the subdiscipline Evo-Devo) in the role of describing how new forms are created.

Self-identification

Science

This is a science in the sense of making systematic observations in comparative studies, and in generating mathematical models in the population genetics subdiscipline.

Characteristics

Evolutionary biology is a distinctive scientific discipline in that it is concerned with historical subject matter.

Relevance to Science and Religion

Evolutionary biology is related to “Science and Religion” because it has implications for, and discusses, the origin and evolved nature of human beings. As well, it is a science that establishes beliefs about past events, and all beliefs have numinous functions.

Sources of Authority

The sources of authority in evolutionary biology, as in any science, are important published works and the authors who wrote them. These persons move to positions of power in regard to controlling publication and resource allocations. As well, they determine the direction that investigations will move in.

Ethical Principles

Ethical principles guiding this discipline, as in any science, have to do with abhorring plagiarism and in maintaining focus (excluding overly creative approaches and new departures). At the same time, competition is extolled.

Key Values

The overriding key value in this discipline is competition. This is central to the dominant (neo-Darwinian) theory of evolution, as competition between genotypes for representation in future populations.

Conceptualization

Nature/World

“Nature/world” does not function prominently in evolutionary biology inasmuch as it excludes the origin of life from its studies.

Human Being

“Human being” is important inasmuch as it studies the origin of humanity.

Life and Death

“Life (and origins of) death” are important in that the neo-Darwinian theory has a theory of why senescence occurs, and that leads to death.

Reality

“Reality” is not, as such, important in evolutionary biology.

Knowledge

“Knowledge” has some importance inasmuch as the “meme” analog of the gene is held to spread through populations by way of competition between ideas.

Truth

“Truth” has no role in this, or any, scientific discipline. All observations and theories are

implicitly held to be faulty in some way, and may be jettisoned or improved at any time.

Perception

“Perception” is the subject of some studies in the ethology subdiscipline of evolutionary biology. For example, while we have three color receptors in our eyes, birds have four.

Time

“Time” is important in evolutionary studies inasmuch as biological evolution has taken place over long periods of time, while studies that can be done covering many generations are restricted to microorganisms in experimental setups, or to computer simulations.

Consciousness

“Consciousness” has no presence in evolutionary biology.

Rationality/Reason

“Rationality or reason” is studied in regard to its functions in the “evolutionary psychology” subdiscipline of evolutionary biology.

Mystery

‘Mystery’ has no presence in evolutionary biology.

Relevant Themes

Additional themes, issues, and concepts in evolutionary biology of relevance to “Science and Religion” concern (a) mass extinctions that have periodically decimated life on Earth, and could happen again, (b) widespread extinctions currently being caused by human economic activities, and (c) human predispositions that appear under crowded conditions.

Evolutionary Prototyping

Linda Sherrell
Department of Computer Science,
The University of Memphis, Memphis, TN, USA

Evolutionary prototyping is a software development method where the developer or development team first constructs a prototype. After receiving initial feedback from the customer, subsequent prototypes are produced, each with additional functionality or improvements, until the final product emerges.

This prototyping scheme differs from the rapid or throwaway prototyping, in that the developer begins with the best understood requirements; whereas in rapid prototyping, the developer implements the least understood requirements. Furthermore, the first prototype need not be built quickly.

Note that evolutionary prototyping is similar to incremental development in that parts of the system may be inspected or delivered to the customer throughout the software life cycle model.

Description

Evolutionary psychology (EP) is a general theoretical approach to psychology. It is the application of Darwinian principles to the understanding of human nature. Simply put, EP claims that we humans think and behave as we do because evolutionary pressures molded and adapted us to be that way. EP is an approach to psychology that seeks to provide a comprehensive, unifying framework for understanding human behavior and mental processes.

EP sees itself as grounded in the most successful unifying framework of the life sciences: neo-Darwinism. Neo-Darwinism has been used as the theoretical structure uniting all of biology, and its effects are being felt in areas as diverse as anthropology, economics, and even cosmology. As the organizing framework for biology, neo-Darwinism applies to all living organisms on Earth. The assumption that humans fall outside of this framework is, for EP and its adherents, special pleading in the extreme. To further bolster their position, evolutionary-minded psychologists (here on EPers) can point to an impressive body of

empirical support that has accrued over the past few decades. This empirical support has cut across all subdisciplines of psychology. From the earliest work in mate selection and attraction, the evolutionary approach has been successfully applied to questions in developmental psychology (e.g., why do girls mature more quickly than boys?), social psychology (e.g., why do we so easily form in-groups and out-groups?), cognitive psychology (e.g., why is calculus so much more difficult to learn than language?), biological psychology (e.g., why is the frontal lobe so much bigger than the occipital lobe?), and even abnormal psychology (e.g., why are we more likely to have phobias to snakes and spiders rather than cars and guns?).

Most recently, the evolutionary approach has been delving into our most human of characteristics: morality, religion, and consciousness. Though some have argued that these topics are “beyond” scientific explanation, recent work has given EP a solid foothold in each. For example, morality is a natural part of our social nature. Those of our ancestors who simply couldn’t figure out that repaying debts made others angry or being obviously selfish made one a poor mating prospect, suffered social isolation and reduced fitness. Similarly, religion may have been important for bolstering group-based moral standards making one group more cohesive and therefore more successful compared to another. How far EP can successfully be pushed is still an open question. No doubt it will eventually run into limitations of one sort or another. But as for now, EPers see their approach as the most exciting theoretical advancement yet in psychology.

Self-identification

Without question, EP sees itself as science. This is so because it generates hypotheses that can be empirically tested.

Characteristics

What makes EP distinctive is its promise. From the EP perspective, psychology has stumbled

around for decades as a loose collection of subdisciplines with only a minimal amount of constructive interaction among themselves. EP holds a promise of providing a common theoretical framework for uniting all of psychology. For the first time in history, psychologists might have a common language that they can use to relate to one another. Furthermore, EP strengthens the connections between psychology and other related disciplines such as biology, anthropology, primatology, and even archeology. A common theoretical framework and a common language can help specialists from different disciplines and subdisciplines work together rather than in suspicious isolation from each other, thus facilitating progress.

Relevance to Science and Religion

There are a number of reasons why the science/religion dialogue is of interest to evolutionary psychologists. First, religion is a nearly universal characteristic of human societies. As such, it affects the thinking and behaving of the vast majority of humanity. Ignoring religion leaves psychology as an incomplete science. Put another way, to fully understand humans, psychology must investigate religion. The fruits of this investigation will very likely play an important role in shaping the issues relevant to the science/religion dialogue. For example, the empirical studies showing positive physical and mental health benefits associated with religious practice can inform discussions of both the functional significance of religion in peoples’ lives and the potential evolutionary origins of religion.

Second, religion did not just appear fully formed – it evolved. The same is true for the mental faculties that allow humans to think religiously. The question of how humans became religious creatures is inherently a question of evolutionary psychology. Exploring the ► [selection pressures](#) that molded us into creatures capable of religious imagination informs us about our evolutionary past and helps us to better understand the role that religion plays in today’s world. Finally, exploring the evolution of religion can

provide a scaffold for constructive interaction among many different scholars both religious and nonreligious. For believers and theologians, it may provide an opportunity to better understand how religion (presumably guided by divine providence) emerged, or was revealed, among our ancestors. For scientific skeptics, it may offer an opportunity to better understand the natural basis of religion and the seemingly mysterious human need for it. Both groups, however, can be united in these efforts by using agreed upon scientific methods for addressing questions about why and how humans evolved as religious creatures.

Sources of Authority

Being grounded in neo-Darwinism, the writings of Darwin (*Origin of Species*, *Descent of Man*) provide the foundational texts. William James was one of the few early psychologists to take evolution seriously as an important mechanism molding human nature. His writings – *Principles of Psychology*, *Varieties of Religious Experience* – form another layer of the early important works. In more recent times, E. O. Wilson's *Sociobiology* and Richard Dawkins' *The Selfish Gene* lay-out some of the important principles of neo-Darwinism and its application to human behavior. William Hamilton's work on inclusive fitness and Robert Trivers' work on parental investment and reciprocal altruism have provided important contributions in understanding how a "selfish" evolutionary process can create "selfless" behavior. Barkow, Cosmides, and Tooby's edited volume *The Adapted Mind* provides a good overview of evolutionary psychology for the professional audience. While a very recent handbook (2005), edited by David Buss called *The Handbook of Evolutionary Psychology*, provides a state of the field report in just about every subdiscipline of psychology.

Ethical Principles

The ethical principles guiding EP are no different from those guiding any other scientific discipline.

Practitioners in EP are expected to conduct research with competency and integrity. Because EP deals directly with human nature, those involved in EP research bear an especially heavy burden in being honest, cautious, and thorough in their data collection and interpretation. It is not uncommon for EP research to have sensitive social and political implications. It is all too easy for the general public and/or the popular press to sensationalize, misunderstand, or exaggerate EP studies in an attempt to sell a product or push an agenda. For example, studies indicating that by virtue of our evolutionary design males are naturally aggressive or females are naturally deceptive are sometimes carelessly transformed from studies trying to explain why certain behavioral propensities exist into ones offering a justification for some of our less socially desirable tendencies. EP researchers must take great care in delimiting the scope of generalizability of their work, and they must be constantly sensitive to the wide individual differences typically present in humans. The need for replication of findings, restraint in interpretation, and strict discipline in distinguishing natural tendencies from moral prescriptions are essential in EP.

Key Values

The key values would be curiosity and honesty. Psychologists who adopt an evolutionary approach must be curious about human nature, and this curiosity must drive them to seek the best explanations possible for why humans are the way we are. Furthermore, EPers must be honest about human nature. Humans have a naturally evolved collection of both admirable and ignoble traits. This is reflective of the fact that evolution is an adaptive process, not a moral one. At the same time, EPers must be careful not to confuse "how we naturally are" with what we potentially can be. For example, though we have natural tendencies toward selfishness, vindictiveness, and prejudice, we also have natural tendencies toward compassion, forgiveness, and justice. By studying moral exemplars such as Gandhi, Mother Theresa, and Nelson Mandela, EP can

provide important data on how it is that humans can enlarge the more admirable of our qualities while restraining our more vile ones. What we are naturally neither determines the ultimate manner of our being nor justifies our more shameful tendencies.

Conceptualization

Nature/World

There are a number of ways in which the EP perspective on these terms is somewhat different from how they are commonly used. First, in one sense, nature and world are to EPers pretty much the same as they are to anyone else. Nature is the natural stuff out there: forests, streams, birds, and mountains – all the stuff you want to “get back to” when you go camping. World is often taken as being broader, encompassing both our human-made urban environments (“man’s world”) and the “natural” world. However, in another sense, EP offers a slightly different perspective on both these terms. Since from an EP standpoint, humans are not radically set apart from other species, our habitat is also not radically set apart from “nature.” In other words, all habitats are natural. The entire world from an 80-story office tower in Chicago to a tangled jungle canopy in the Congo is natural. Habitats may vary in terms of how much a species has manipulated the environment to suit its own needs (humans and beavers tend to manipulate their environments more than dragonflies and coyotes). Manipulation, however, is not the same as making something unnatural. As an environment is manipulated, the kind of selection pressures it brings to bear on various species changes. Generally speaking, the species doing the manipulating does so to make the environment more suitable for itself, and often this will make the environment less suitable for other species. So as beavers reduce river flow, species that depend on the river flow may suffer. As humans build 80-story office towers, species that formerly used the trees or open space on which the building now sits suffer.

Furthermore, EP often makes a distinction between the world humans now inhabit and the

world to which we were originally adapted. *Homo sapiens* emerged some 200,000–150,000 years ago. It has only been in about the last 8,000 years or so that settled agriculture emerged. Thus, for over 99 % of our evolutionary history, humans lived in hunter-gatherer bands – and it was this world, called the ► [environment of evolutionary adaptedness](#) or the EEA, to which we were adapted. This ancestral environment is the one which is “natural” to us in the sense that our mental and behavioral tendencies are designed to fit with it and not necessarily with the modern urban world.

Human Being

As with nature/world, there is a sense in which the term human being is the same for EPers as it is for anyone else. Human being refers to us, members of our species. However, there is another sense in which human being is a much more technical and nuanced term for EPers than for most others. Human beings are members of the species *Homo sapiens sapiens*. This species arose about 200,000–150,000 years ago and differed only very modestly in morphology (body form) from other ► [hominin](#) species also present at that time (e.g., *Homo erectus*, *Homo helmei*, and *Homo neanderthalensis*; collectively these species are often referred to as the archaic *Homo sapiens*). The diverse array of hominin species present both prior to and concomitant with the emergence of *Homo sapiens sapiens* debunks any notion of human evolution as a progressive march from less intelligent and sophisticated species to increasingly more intelligence and sophisticated ones. Indeed, upon their initial emergence, *Homo sapiens sapiens* did not differ at all in terms of stone tools, artifacts, hunting strategies, or other archeological indices of cognitive capacity relative to other contemporaneous hominins.

Thus, a major question in EP, and human evolution in general, is what variable(s) account(s) for our unique human intellectual capabilities. When and why did we become human, and what exactly does that mean? By the time of the ► [Upper Paleolithic](#) (about 35,000 years ago), symbolic artifacts and stunning cave art reveal a mind that is undeniably human – the same as ours now.

But why did it take so long and what prompted its emergence then and not sooner or later?

Life and Death

While the origin of life is a fascinating and important topic, it is not directly relevant to EP. All evolutionary processes pertain to the diversification of life forms; thus, life – understood as a self-sustaining system capable of reproduction or replication – is a necessary prerequisite for evolution. Death or the loss of a system's self-sustaining and reproductive ability is also an essential aspect of evolution. Less adapted creatures tend to die out with relatively less reproductive success compared to more adapted creatures. Thus, the traits associated with the less adapted creatures are less likely to be passed on to future generations.

Reality, Knowledge, Truth, and Perception

These four terms are interrelated in EP. Evolution designs creatures to be adapted to their environments. This typically means that to one degree or another, creatures have to take in information from the environment and respond to that information in ways that enhance their fitness or reproductive success. Perception refers to all the processes that go on in an organism directed to the purpose of taking in and making sense out of external stimulation. Knowledge refers to the interpretation that organisms give to that external stimulation based both on the sensory inputs and the stored results of past interactions with the environment. This knowledge frames the reality within which the organism functions. For example, a rabbit may perceive through both visual and auditory signals the presence of a large four-legged furry creature in its immediate vicinity. Based on this input coupled with information retrieved from memory about past encounters of a similar nature, it may construct knowledge about the presence of a predator (it knows a fox is about). This knowledge provides the basis for its current reality – it is in trouble and needs to react quickly. For the rabbit, the danger is real and so it runs away. It is at this point that evolution, in a sense, stops.

The question of “was the danger really real?” or, put another way, was the rabbit's reality true is

not terribly relevant for evolutionary purposes. The only thing that is relevant, from an evolutionary standpoint, is whether the reaction (running away) based on the assumed reality (danger present) is more adaptive than a different reaction based on different assumed reality. In this sense, it can be said that evolution is more “concerned” with pragmatic truth (what works in terms of promoting fitness) rather than metaphysical truth (what is absolutely true).

As an example, suppose another rabbit was a “tough guy” rabbit who would only run away if there was thoroughly convincing evidence of a fox (as opposed to an opossum or raccoon) about. This might have the advantage of conserving energy for only those times when one is really in danger. However, since the margin of error on this strategy is far thinner (a single mistake could be fatal), the chances of this rabbit's alternative strategy for interpreting reality getting passed along to future generations are less than its more paranoid comrade.

Thus, we are led to a conclusion about evolutionary processes: they hone an organism's mental/perceptual processes such that they are adaptive, not necessarily so they discern the “truth.” Often a fairly accurate (or truthful) assessment of the environment is more adaptive than an inaccurate (or nontruthful) one (avoiding falling off a cliff that is really there is quite adaptive). However, this need not always be true. Most EPers see very little convincing evidence that any creatures, other than humans (and maybe elephants), know they are going to die, even though this is undeniably true. Knowing that truth would probably not be adaptive – the worry would sap energy needed for more immediate tasks. Thus, truth and adaptiveness are not the same, and so just because a certain interpretation of reality is adaptive, there is no guarantee that it is the truth. This discussion becomes very relevant when we consider issues of God, religion, the soul, etc. Believing that these concepts are true might be adaptive, but that doesn't necessarily mean that they are really true. It doesn't necessarily mean that they are false either; it just means that we can't use adaptive as convincing evidence for truth.

Time

For EP, time is often considered on a much deeper scale than is commonly done. Humans as a species have been around for about 200,000 years. However, placed against the time scale of life on Earth (about 3.5 billion years), it is a miniscule proportion. Furthermore, since settled agriculture only emerged about 8,000 years ago, then the kind of lifestyle that we are currently engaged in makes up only a tiny portion of the total time that humans have been around. Thus, human civilization, which we typically think of as being very old, is, in fact, only a tiny blip in relation to the deep time of Earth's total history.

Consciousness

From the perspective of EP, consciousness is something of a mystery. Psychological studies show that many processes can be carried out quite effectively unconsciously. Furthermore, some of the most abundant and well-adapted creatures (bacteria, beetles, and cockroaches) have little, if any, consciousness. So why be conscious? The importance that consciousness has for humans (one might easily argue that it is the central human trait) suggests that it must serve some adaptive function. But isolating exactly what that function is has not been easy. Some studies suggest that consciousness is necessary when acquiring new, complex skills. This, however, is not a guarantee that consciousness arose for that purpose or that it arose for any purpose at all.

Rationality/Reason

EP considers reason to be an adaptive trait that allowed humans to better interact with their environments. Furthermore, studies suggest that it was the social environment that was key in selecting for human rational functioning. Reasoning problems that are framed in terms of social obligations (if he or she is a teenager, then he or she must not be drinking beer) are usually more easily solved than the ones framed more abstractly (if the card has a vowel on one side, then it must have an even number on the other). This suggests that our reasoning ability

evolved to help us solve social problems and to ensure that we were not getting cheated by others. This may help to explain why it seems so effortless (and even fun) to gossip and speculate (reason) about why others did what they did (Fred must have thought that Jenny cheated on him when he saw her at the party with Ted). Yet at the same time, reasoning about why the sum of x must equal the square root of y on the other side of the equation is often arduous.

Mystery

In EP, mysteries usually surround particular human traits such as consciousness, language, morality, religious tendencies, etc. Why and how did these particularly human characteristics arise? Complete explanations may never be found. Yet it is precisely the mystery surrounding these issues that makes them especially interesting for EPers to pursue. Mystery in the largest sense involves the very origin of the evolutionary process itself. Why have such a process and from where did it originate? Is there any purpose to evolution or is it just an aimless, futile march of adaptation, diversification, and extinction? These are the deepest mysteries and ones where science (and certainly EP) is hard pressed to provide any answers.

Relevant Themes

There is considerable discussion concerning the evolutionary origin of religion. Some have argued that religion may have provided an adaptive advantage in terms of group cohesion and solidarity. If so, then this suggests that religion was itself an adaptation. Furthermore, it suggests that some form of group level selection may have been operating in our ancestral past. This would cut against the dominant orthodoxy of individual selection being the proper level of analysis for understanding evolutionary processes.

Others have contended that religion represents not an adaptation but an exaptation or spandrel. ► **Exaptation** refers to a trait that emerged for one adaptive purpose being co-opted later for

a different purpose. So, for example, the bones of our middle ear originally emerged as part of the hinge system for reptilian jaws. Later, this set of bones served nicely as a mechanism for conducting sound vibrations (although that is not what it was originally designed to do). A ► [spandrel](#) is similar except that its origin need not have involved any adaptive purpose. Today, we can find all kinds of uses for our belly buttons (paint them, put rings and diamonds in them, etc.), and social trends being what they are, belly buttons might become identified with sexual appeal such that those with better buttons might even have higher rates of ► [reproductive success](#). None of these functions, however, explain why belly buttons originally arose. As best as we can tell, they are just accidental by-products of our anatomy without any direct adaptive purpose.

From EP's perspective, religion may be something like this. Humans may first have evolved the mental capacity for ► [agency detection](#) (ascribing behavior to an internal mental state such as a desire or belief) for the purpose of understanding and predicting the behavior of other animals (including fellow humans). Later, this capacity may have been extended to include environmental events such as the wind, rain, or ocean currents. Thus, the wind was assumed to have a desire to punish humans for sin or reward them for virtue. From this beginning, more complex ideas about spiritual forces and deities could emerge. Debates over the origin of religion reflect its complexity as well as the complexities of the evolutionary process itself.

Introduction

Evolutionary Theology (ET) refers to forms of religious self-reflection that are significantly shaped by the resources of evolutionary biology. While some evolutionary theologies build on assumptions of non-Darwinian forms of evolution such as orthogenesis and spiritual

goal-directedness, most contemporary proponents of ET give preference to standard neo-Darwinian models of evolution with its focus on natural selection, the statistics of variations of environments and genomes, and the malleability of species over time. However, since evolutionary theory itself is under constant development, and also find various interpretations within contemporary philosophy of biology, proponents of ET also refer to aspects of biological evolution that go beyond neo-Darwinism, such as the importance of biochemical constraints, self-organization, and the much debated question of trends toward complexity in evolution. Also, more often than not, theological proposals refer to central aspects of cultural evolution, such as the emergence of symbolic language, morality, aesthetics, and religion.

In order to constitute a theology in the proper sense of the word (involving concepts of the God or the divine) ET inevitably draws on other sources than evolutionary theory, such as religious experiences, scriptures, and traditions. ET is nevertheless distinct from forms of theology that are either indifferent to the findings of evolutionary biology (such as existentialist theology), or anti-Darwinian in nature (such as Intelligent Design theory). Even though the latter may be said to be shaped by Darwinism, evolutionary biology is here not used as a positive resource for theology.

Early Evolutionary Theology

The first examples of ET can be found in the earliest responses to Darwin's theory of evolution. Darwin sent a draft of the *Origin of Species* (published November 24, 1859) to Charles Kingsley, a close friend from Darwin's days as student of theology. From his parsonage, Kingsley wrote a congratulating letter to Darwin: "I have gradually learnt to see that it is just as noble a conception of Deity, to believe that he created primal forms capable of self-development into all forms needful *pro tempore* and *pro loco*, as to believe he required a fresh act of intervention to supply the *lacunas* which he

himself had made. I question whether the former be not the loftier thought" (November 18, 1859). God the creator "makes things make themselves," as Kingsley later argued. Already in the second edition of the *Origin of Species* (January 7, 1860), Darwin appropriated Kingsley's words when referring to "a celebrated author and divine" who had written that "it is just as noble a conception of the Deity to believe that He created a few original forms capable of self-development, as to believe that He required a fresh act of creation to supply the voids caused by the actions of his laws" (Darwin 1860: 481). In the concluding paragraph, Darwin also inserted a new reference to God: "There is grandeur in this view of life, with its several powers, having been originally breathed *by the Creator* into a few forms or into one and that, whilst this planet has gone circling on according to the fixed law of gravity, from so simple a beginning endless forms most beautiful and most wonderful have been, and are being evolved" (Darwin's insertion italicized). It has been discussed whether these theological reflections are to be seen merely as strategic compromises. But in his posthumous *Autobiography* Darwin stated that at the time he was writing the *Origin*, "I deserve to be called a Theist," while adding that his religious conviction later "has very gradually with many fluctuations become weaker" (Darwin 1958: 93). He ended up in agnosticism: "The mystery of the beginning of all things is insoluble by us and I for one must be content to remain an agnostic" (1958: 94).

Darwin's impetus for religious reflections mostly came up in relation to the laws of physics, and to the beauties of nature such as the Brazilian rain forest. He thus shared the expectation of a harmonious world order with contemporary Victorianism. On this background, the miseries of pain, and their inevitability given natural selection, were to be seen as counter-indications of a moral divine design. Whereas Darwin's strongest proponent in America, the Harvard Professor Asa Gray, argued for a divine direction of evolution, Darwin himself eschewed the idea of a divine twinkling of the processes of natural selection. His correspondence with Gray gives

ample evidence of Darwin's concession that his own theology was "in an utterly hopeless muddle. I cannot think that the world, as we see it, is the result of chance and yet I cannot look at each separate thing as the result of Design" (Letter to Asa Gray November 26, 1860). Simultaneously, Darwin gave up the idea of a divine revelation in Christianity. His distaste for revivalism was outspoken and uncompromising, in particular the "damnable doctrine" of damnation (1958: 87).

Ever since Darwin pointed to natural selection and variation as the prime engines of biological evolution, a variety of themes came up as potential falsifiers or validations of religion in general, and of Christianity in particular. In what follows, the different challenges and responses are discussed one by one.

The Interpretation of Scripture

Darwin and his followers were by no means the first to question a literal reading of the creation story in Genesis 1–3. The so-called higher criticism in Germany had done so since the end of the eighteenth century, and in England Robert Chambers' *Vestiges of the Natural History of Creation* (1844) had argued that since God works through laws of nature no one should understand the 6-days account of Genesis literally. Darwin's revolutionary theory of evolution was launched in the midst of an age of evangelical revivalism, however, and the interpretation of scripture was heavily debated in the early decades of ET. Even though Darwin did not pretend to solve the riddle of the emergence of life, his mechanisms of evolution required a long history of species formation, including a geological period of minimally 200 million years. Initially, the Darwinians had a time problem that was only solved conclusively much later with the Big Bang theory. But the defenders of a literal reading of Genesis (an individual creation of each species during 6 days, and a time horizon of maximally 10,000 years) soon had to fight against the common views of physicists, geologists, and evolutionary biologists. Catastrophists argued that the laws of nature had been different before and

after the deluge; some argued more defensively that the 6 days might refer to long ages before the creation of humankind (the Hebrew *yom* could mean both days or ages); others straightforwardly believed that God made the world look older in order to test his believers.

It goes without saying that evolutionary theologians found these maneuvers utterly futile. They interpreted the Bible as a foundational myth about the perennial conditions of humanity in relation to God rather than as a textbook of epochs in early natural history. Proponents of ET here usually followed a combination of historical criticism and liberal Protestant theology (Barton and Wilkinson 2009). Today, ET follows a standard distinction between the "common creation story" provided by the sciences, and the "metanarratives" of religion, the latter focusing on the meaning of the cosmos, life, and human existence. Ancient precursors exist for such distinction. The Jewish-Platonic philosopher Philo of Alexandria (c. 20 B.C.E. to 50 C.E.) read Genesis as a description of God's instantaneous creation of a spiritual world that was only later to be manifested in time and space. Church Fathers such as Gregory of Nyssa (c. 331–395) and Augustine (354–430) followed this method of interpretation, assuming that God created an intelligible world (Genesis 1) prior to the creation of the material world (Genesis 2 onward). Symbolic and literal readings were thus often intertwined in Patristic and Medieval exegesis. Against this background, Eastern-Orthodox and Roman-Catholic theology have come to accept the gradual evolution of species, even though the human soul is claimed to be uniquely created simultaneously with each fertilized egg. A literalist reading of Genesis is only widespread among Protestant fundamentalists. Conservative Jewish communities usually accept long-term gradual evolution, while Muslim communities are divided on the issue. Since the Quran only offers vague descriptions of cosmological beginnings, the age of the Earth does not feature centrally in Muslim circles. Islam does host varieties of ET, but according to polls, the majority of Muslim communities are still against evolutionary theory, particularly concerning human descent.

The Common Descent of Humanity

While Darwin left the origins of humanity out of account in *On the Origin of Species*, he addressed the issue at great length in *The Descent of Man* (1871) as well as in the *Expression of the Emotions in Men and Animals* (1872). Darwin here analyzed many structural homologies between humans and other species, while also pointing to behavioral similarities regarding sexual selection, emotions, and instinctive reactions. Darwin found that even religious sentiments are similar to the reactions of dogs coping with sudden changes in their environments. To many of his contemporaries, Darwinism was simply identical with the “ape-theory.”

Proponents of ET have developed several arguments against the view that Darwinism implies a humiliation of the human race. The most principled argument (developed already by nineteenth century Kantians) has been to apply the *fact/value distinction*: The dignity of humanity does not depend on its historical origins but stands and falls with the intrinsic value (or disvalue) of humanity as it is today; just as a daughter of Stalin should not be valued or disvalued by the undertakings of her father, so the value of humanity does not depend on its origins. Even though this argument is valid, the repetitive use of it tends to bolster the dualistic view that what is valuable about humanity is simply that which dissociates us from other animals.

Others have followed an even more straightforward *argument from progress*: Rather than being a story of the descent of man, evolution is a story of the “Ascent of Man” (so the title of Henry Drummond’s Lowell Lectures 1904, also used for a famous BBC series by Jacob Bronowski 1973). Yet also this argument backfires. It could well be, as already assumed by Darwin himself (1958: 92), that the human race is only one station in an evolutionary trajectory that inevitably leads beyond the human race. A similar argument is made today by the transhumanist movement.

The most widespread strategy among evolutionary theists has been to develop a comparative

perspective that is able to value the *continuity* between humans and other higher animals, and to point to marks of *human distinctiveness*. Central aspects of human cognition find precursors and analogies in other species, such as locomotion (including bipedal walk) and the development of sentience (from light-sensitive cells to compound eyes and lens-based eyes). Likewise, in social insects, we find clear systems of division of work with procedures for “punishment” of free-riders among higher apes, and we find forms of behavior that may be termed moral or proto-moral. The comparative perspective even involves cases in which animal development far exceeds that of humanity, for example, in terms of physical strength, the olfactory senses of dogs, and the evolution of forms of awareness unknown to humans (such as echolocation in bats and dolphins). Without humiliating the human species, such evolutionary features may elicit a sense of humility on the part of humanity. Many proponents of ET thus see humanity as being a peer with its co-creatures, and influential theologians such as Jürgen Moltmann have argued that both evolutionary and biblical perspectives require us to understand humanity as carved out of the web of nature (*imago mundi*) before it makes sense to speak of humanity as created in the image of God (*imago Dei*).

What then about human distinctiveness, if not uniqueness? Evolutionary theory does not support an essentialist concept of species. Yet most evolutionary biologists are prepared to admit that *Homo sapiens*, due to historical happenstance, has developed quite unique characteristics that we do not find in other species. “We are built as gene machines and cultured as meme machines,” as Richard Dawkins argued in *The Selfish Gene* (1976), and similar views are held by George C. Simpson, E.O Wilson, and other strict evolutionists. Theologians often argue on similar tracks. Wolfhart Pannenberg points to the human openness to new and fresh experiences within a horizon of possibilities which liberates humans from a bondage to the concrete environments and the instinctual reactions typical for other species. This sense of infinite horizons may also explain the emergence of religion, including ideas about

God. Likewise, Karl Rahner points to the peculiar capacity of human beings to transcend themselves through their latent or “unthematic” awareness of God. This “supernatural existential” serves as a precondition for the specific human capacity for freedom, self-reflection, and universal concepts of truth and morality.

Within current science-religion discussions, the search for human distinctiveness has been elaborated partly in discussion with paleoanthropology, and partly in the context of research programs such as evolutionary psychology and cognitive theories of religion (van Huyssteen 2006). Paleoanthropological records suggest that *Homo sapiens* emerged from a common evolutionary lineage with the *homo habilis* and *homo erectus* (c. 2–1.8 myr) around 400 kyr ago, and was, according to known records, not developed into anatomically modern *homo sapiens sapiens* until around 100 kyr ago. Our species has thus lived together with the *homo neandertalis* (c. 170–30 kyr), who had slightly bigger brains than we. Yet, apparently, a cultural explosion took place only within our species between 60 and 30 kyr ago. Paleoanthropologists argue that cultures constitute systems of nongenetic information transfer, manifested in discrete forms of tool making and art, and in systems of morality and belief that differ from population to population (van Huyssteen 2006: 222). Moreover, cultural information is not only dependent on the brains of individuals, but is stockpiled into forms of cultural memory, supported by social media such as art and architecture, symbolic language, rituals, and signs with socially shared meanings.

While evolutionary psychologists agree that there is a naturalness for developing religious imagination within the human species, they find the explanation for this fact in the “Hyperactive Agency Detection Device” (HADD): Particular brain modules work spontaneously leading to an over-ascription of agency and mind to, for example, stones, trees, clouds, or dreams as revealing “supernatural agents.” Some evolutionary theologians find this explanation plausible and argue for its in-principle compatibility with a notion of a God, who wants to be known to human beings.

Others (probably the majority) find the psychological explanation of the emergence of religion both speculative and wanting in detail, and argue that religion more probably came up in the creative gene-culture interaction, where the immediate pressures of natural selection are relaxed (Rolston 1999: 141). With its laryngeal tract *Homo sapiens* affords a particular capacity for nuanced speech, and the acquisition of a symbolic language during cultural evolution facilitated an awareness of open-ended meanings, including references to principles and universals such as the divine, mathematics, ideas of the common good, and the search for truths that transcend the perspective of the individual persons and particular groups. The emergence of religion (as evidenced in burial practices) and moral sociality (as evidenced in rituals and community building) feeds into this picture. As in natural selection, not everything goes in cultural evolution. Religion and morality have thus been pruned and universalized in the course of cultural evolution, so that only relatively few ideas of the divine have been able to survive the test of time and experience. Also, religious wisdom traditions provide large-scale orientational schemes which enable humans to cope with everlasting dilemmas of the human condition, and to pick out information about what is of enduring value in contrast to what is only of ephemeral importance.

Design, Chance and Natural Selection

The issue of design versus natural selection plus variation has remained a contested area in ET. Both believers and nonbelievers have thus argued that if Darwinism is correct, divine purpose and care are removed from the world of living organisms to be replaced by purposeless chance and pitiless selection. The picture is oversimplified, however. For even though Darwin’s mechanism of natural selection superseded divine design as the basic framework for explaining the fertility, growth, and order in the world of biology, Darwin himself spoke of a design in the general setup of the universe. Since the late 1950s, physicists have

unexpectedly reinvigorated discussions of design by pointing to the so-called *cosmic fine-tuning* of laws and physical constants, which provide the proper physical and chemical conditions for the emergence of life and consciousness. Moreover, mathematical models have been developed in order to explain recurrent features of self-organization and *trends toward increased complexity* during evolution (Gregersen 2003). The so-called anthropic principle points to the concerted fitfulness of the basic laws of nature (gravity and nuclear forces) and of the constants of nature (mass-energy) for the biological habitability of the universe. Whereas the biological community earlier tended to think that life and human existence emerged as an unlikely result of chance, the majority of scientists today believe that we live in a biofriendly universe, so that life emerges inevitably given the physicochemical conditions. Rather than seeing humanity as a tragic gypsy fighting against all odds with the conditions of the universe (so Jacques Monod), it is nowadays more often assumed that we are at home in the universe (Stuart Kauffman), and that the emergence of life is almost inevitable (Christian de Duve). Obviously, this view is open to naturalist as well as to theistic interpretations.

The anthropic principle can be reformulated as a research program asking, How much could the constants and laws of nature be changed, and we would still have life and consciousness? The answer of physics is: very little indeed. Based on the fact of the concerted laws, a new argument for design has been developed: (1) The more improbable the specific laws of nature are (in relation to other mathematically possible laws), and (2) the more these very particular laws are actually fine-tuned for life (toward the inevitability of life and consciousness), the stronger is the argument for an inference to design. No inference, however, offers a proof. Thus, it could be that the laws of nature are as they are by sheer chance (the Lady Luck Hypothesis) or it could be that our universe is only the lucky winner among endless other universes that we do not, and probably never will, know about (the multiverse theory). Anthropic design is thus only one of several explanatory hypotheses, and

considerations of plausibility and economy will depend on worldview assumptions that exceed the scope of empirical science.

The idea of *self-organization* is often presented as the antidote to the idea of design. This is correct as long as one by design understands a controlling preordering of things. Yet, any self-organizational processes takes off from conditions that are difficult to understand to be results of preceding self-organizations, conditions such as the mathematical envelope of possibilities, the physical constants and the laws of nature as we know them. Even if physicists should find a grand unified theory for gravity and quantum laws, which could also explain the amount of matter in the universe, such imaginable “law of everything” would be as it is, and has always been. Yet, even if self-organization can hardly explain all of physics, computer models of self-organization have succeeded to explain quite a few robust features of biological evolution. Evolutionary novelty thus tends to come up in semi-stable and codependent systems poised between evolutionary stable strategies (ESS) and purely chaotic systems.

The new sciences of computational complexity have thus given hope to explain the fact that evolution eventually evidences an overall *complexification* over time, measured by parameters such as size of organisms, morphological complexity, kinetic complexity, complexity of nervous systems and sensitivity, social complexity, and the intensity of interconnectedness between different biological organisms. On the whole, the history of evolution offers both cases of resilience and self-repetition and of novelty and exploration of new adaptive spaces. As evidenced in cases of *convergent evolution*, not everything is up for grabs in evolution. Natural selection is always constrained by what is physically and chemically possible. Some biochemical structures thus show a remarkable self-identity across phyla (such as the *hox*-gene responsible for the building of body structures), while other biological functions have developed independently in different genetic lineages (such as the construction of lens-based eyes in octopus and mammals). Even if the ecological niches

differ markedly, similar adaptive spaces are explored by genetically distant biological classes.

ET stands and falls with its assumption that the interplay between *natural selection and chance* plays a central role in God's manner of letting the world of biology flourish. This core assumption can take several forms. In its strongest form, it is argued that natural selection plus chance by themselves provide the divine ruling of the biological world by *guaranteeing a progress* and proliferation of the biological potencies of the material world. Around the turn of the nineteenth century, this combination of natural selection and a progressivist teleology (often based on Herbert Spencer's interpretation of Darwin) was widespread among liberal theologians (e.g., the aforementioned Henry Drummond).

The medium-strong version is that natural selection plus chance involve a *statistical tendency* to provide some sort of overall *directionality* during evolution, even though one should expect many cases of downfalls, as it is evidenced in the big periods of extinction during evolution (99% of known species are extinct). Observe that directionality is more than equiprobability but less than progress. Many contemporary proponents of ET follow this line. Arthur Peacocke, for example, has persistently argued that the biological notion of chance refers to genetic mutations as well as to the variations facilitated by circumstances and ecological niches. Chance, in this sense, has nothing to do with existential feelings of estrangement and purposelessness, as presupposed by atheists such as Bertrand Russell or Jacques Monod (Peacocke 2004: 50–65). On the contrary, only the principle of chance and variation can open up the full gamut of evolutionary possibilities by generating new organismic constellations which then are subsequently tested in the competitive game of natural selection.

The weak or minimalist version of the core ET assumption is that natural selection and chance are *compatible* with theism. Natural selection and chance are here seen as the *de facto* methods that God has chosen in evolution, this method being coherent with the religious affirmation of divine purpose concerning the outcomes of evolution.

The “how” of the evolutionary mechanisms and principles as described by the sciences are thus complemented with a theological interpretation of the “why” of evolution. The religious question of purpose thus depends on the qualitative or “poetic” outcomes of the evolutionary processes rather than on its quantitative or “prosaic” methods. This path is taken by those who follow Stephen J. Gould and others who argue that the Modern Synthesis of Darwinian macroevolution and genetic micro-evolution is not complete, though not incorrect. The history of evolution is a “drama” (Celia Deane-Drummond) with endless many mutations (at micro-level) and historical “saltations” (at macro-level). On this view, the religious interpretation should acknowledge the tensions, paradoxes, and back-falls of evolution rather than construct a smooth and optimistic trajectory of evolution.

The way ET copes with natural selection and chance can be seen as a theological redescription of an evolutionary process already described and (partially) explained by the sciences. So far, theological hermeneutics stands in the foreground. Yet this hermeneutical approach can be complemented by theories of divine agency during evolution. Robert John Russell et al. (2008) argue that since many mutations occur due to quantum mechanical processes, mutations and variations should be explained at deeper explanatory levels than those offered by the biological sciences. Moreover, since quantum events are the basic constituents of nature, there is at quantum level eventually no difference between the primary and secondary causality (i.e., between the divine creativity, and the actual quantum events). Finally, since quantum events are statistical in nature (even if they all fall within the spectrum of the Schrödinger equation), one cannot ever, according to the Copenhagen interpretation, gain a complete deterministic theory of quantum events. By implication, one can never have full biological explanation of mutations. According to Russell and colleagues, quantum mechanics thus makes a substantive divine agency conceivable also in the biological realms of chance and mutations, a possibility opened up by the Copenhagen interpretation. It is

noteworthy that also some Islamic scholars put emphasis on mutations rather than on natural selection (Guessoum 2011: 290). Although the Quran gives preference to ideas of cosmic balances, mutations are seen as indicators of a sovereign divine agency, which works, as a hidden variable, alongside the standard operations of the laws of nature.

Natural Selection and Natural Evil

Any theory of particular divine agency in evolution inevitably raises the stakes for an evolutionary theodicy. For how can a benevolent creator promote a biological world, in which pain and suffering is part of its working method? Since Darwin himself shared the harmonious expectations of a Victorian natural theology, he was lifelong affected by this theodicy problem. Also today evolutionary biologists argue that the existence of widespread and systematic pain in the universe is what one should expect, if there is *no God* of the universe (Richard Dawkins).

Several evolutionary theodicies have been proposed. One way is to give up the moral expectation to God shared by morally concerned atheists and believers when posing the theodicy question. If God is being-itself, God is both the ground and the abyss of any particular being. This *ground of being-theology* either argues that talk of divine love is symbolic (Paul Tillich), or that moral characteristics of God are altogether misplaced. God is amoral rather than unmoral. This theological position finds some support in the Bible (Isa 45:8: “I make weal and create woe”) and thus also Martin Luther and John Calvin referred to the “hidden God.” These Reformation theologians, however, made a distinction between the hidden and the revealed God, and the task of faith was to believe in God’s revealed love while accepting the tension between experience and faith.

Another path consists of distinguishing between *evil* and *hardship*. On this view, the fact of natural suffering does not suggest that God has evil intentions, or even finds pleasure in designing miseries. Rather, natural evils are

unavoidable by-products of evolution. Just as one cannot create morally free creatures without also risking their immoral deeds, so God cannot create a world endowed with freedom and autonomy without facing natural evils. This *free process defense* involves that pain and pleasure come and go together, part of the package deal of creation. God is neither immoral nor amoral, but values the world as a whole as “very good” (Gen 1:31). This position then finds two different interpretations. One is to endorse the cruciform character of creation, and argue that the pain of the prey is redeemed by the pleasure of the predator within the evolutionary process; a world of sweat and blood is better than a bloodless world (Holmes Rolston). Another option is to see God’s compassion and co-suffering as the divine response to natural evils. A Christian ET may thus say that in Jesus, the Son of God, God is co-carrying the costs of evolution while taking side with the losers of the game of biological and social completion. Similarly, non-Christian philosophers of biology have observed the common emphasis on the centrality of suffering in Darwinism and in Christianity (Ruse 2001: 134).

On Christian premises, it is even possible to elaborate a Trinitarian theodicy in three steps. In the beginning God said, “Let it Be”: Let the world develop and flourish (the free process view of creation). For the benefit of the evolving creation, however, God goes into the depths of evolutionary existence through his own Son, thus sharing the “groanings” and birthing woes of creation (Rom 8:22–23) while also absorbing and transcending the pains in God’s internal experience (cross and resurrection of Christ). Finally, God will send his life-giving Spirit to create a new world under new cosmological conditions while retaining the experiences of lived life, with both scars and joys (the new creation) (Southgate 2008).

Unsolved Metaphysical Questions

As we have seen, proponents of ET follow a variety of strategies by which they appropriate central tenets of evolutionary theory within

distinctive theologies. Accordingly, the term “evolutionary theism” is only to be used as a shorthand for quite different ways of using evolutionary biology as a resource for religious self-reflection. In fact, none of the described positions use evolutionary biology as their only source for theological reflection a commitment to Darwinian evolution as the best available scientific theory does not imply the view that evolutionary theory is the solution to all sorts of questions. Not only does physics and chemistry precede and undergird all forms of life through cultural formations but human beings have developed forms of life and experience that cannot be sufficiently tackled by evolutionary biology. If there is a common core to ET, it is the assumption that evolutionary theory needs to be seen in a wider metaphysical perspective, involving other natural sciences, the manifold perspectives of the human sciences, and the religious experiences of humanity. Here one needs to dig “deeper than Darwin” (John Haught).

ET also shares an ontological commitment with nontheistic spiritual traditions such as Buddhism. For biology consciousness is a secondary issue that only develops as a sub-form of life in specific lineages, humans in particular. Yet, both the idea of God in the theistic traditions and the idea of the primordial mind in Buddhism presupposes aspects of ultimate reality which are prior to what emerges and come to flourish in very late stages of cosmic evolution. There must be something significantly prior in order for something significant to evolve.

Exaptation

Matt Rosano

Psychology Department, Southeastern Louisiana University, Hammond, LA, USA

Refers to a trait that emerged for one adaptive purpose being co-opted later for a different purpose. For example, the bones of our middle ear did not arise specifically to conduct sound pressure waves. Instead, they were originally part of the reptilian jaw bones designed for chewing. The hinged arrangement, however, proved useful much later for sound propagation and was “re-tooled” by natural selection for that purpose.

Existentialism

[Philosophy of existence](#)

Description

Existentialism, as a philosophy of life, has its idea-historical sources in German idealistic philosophy. Kant, Fichte, Schelling, and Hegel gave the decisive impulses for the birth of existentialism. Kant (1724–1804) moved away from what was understood as medieval metaphysical ontology, ungrounded speculations about the nature of the beyond, and he turned to the analysis of perception and grounds of knowledge, this being the subjectivist turn in him. Heidegger (1889–1976) classifies Kant as an adherent of the philosophy of consciousness, and given the subjectivist turn this seems plausible. In Kant, possibilities and limits of *human experience* and of *perception* are in focus. He asked how the mind “in advance,” *a priori*, structures the perception of the world; his aim was both to show *how* the mind works and how the factory of mind looks like prior to actual perception (Kant 1982). Existentialism draws attention to the preceding domain as well, but it adds *existentialia*, which are beyond the categorical frames. *Existentialia* are like categories, Heidegger wrote, they are transcendental in relation to everyday experience and awareness, but in Heidegger’s view they were more fundamental for human self-understanding than categories. Categories are subjectively in the mind; *existentialia* structure the self/world interaction or human existence in its entirety, and they give access to being. By focusing on *existentialia*, Heidegger considered that he had moved beyond the philosophy of consciousness: in

understanding human existence (*dasein*) in terms of *existentialia*, a clearing of being comes to pass, which does not happen in the philosophy of consciousness! Existentialism, as Heidegger interprets it, is an existential/ontological analysis of being; existentialism is not subjectivism (Heidegger 1985).

To Kant’s subjectivist turn, existentialism adds the existential turn: the analysis is directed to human existence, not only to the mind. Schelling (1775–1854) had claimed that being could be known in existence through experience; there is an *a posteriori* philosophy of “higher empiricism” (Schelling 2007). Experience is not only a passive receiving according to Schelling, but an active *deed of self-determination*. Both Kierkegaard’s and Sartre’s existentialism has radical *a posteriori* character. Claiming that existence precedes essence, Sartre seems to agree with Schelling: human essence is realized through deed, action, and choice only; choice gives human nature its “whatness” or being; existence precedes essence (Sartre 1946). Heidegger on his side claimed that the distinction between essence and existence has haunted Western thought from its beginning. If essence is understood as a pre-given “entity” or abstraction, as a “what” and as a thing, then essentialism is unavoidable according to Heidegger. If we on the other hand understand essence from the perspective of time, then the existential clearing of the essence of humanity and of being is possible according to Heidegger, and such clearing have happened, happens, and will happen in philosophy (Heidegger 1993). That the humanity of humans is dependent on their choices, on their ability to self-determination, is a central theme in existentialism.

Schelling initiated the historicity of philosophy: the place of thinking is in time and space. Existence could be known only in and through existence itself, not through reason alone; existence is to be known in the *phenomenon of existence*. The Greek word for “phenomenon,” φαινόμενον, is translated as “that what shows itself.” Existentialism is closely related to phenomenology and hermeneutics; today, it is more in agreement with post-phenomenology

(Deleuze, Guattari, and Levinas) than with Husserl's phenomenology. Existentialism is thinking in time and place; it tries to express the basic phenomena of human life; it explicates that what show itself in human existence, including being. Existentialism in Heidegger's interpretation is an existential ontology.

For Feuerbach (1804–1872) and Kierkegaard (1813–1855), Schelling's existential turn became crucial. Human beings are in time and space: we think, feel, and will as concrete *bodily beings* in the concrete physical reality; to exist is to *apprehend*, to sense the concrete physical being; human nature (*wesen*) “dwells” in the concrete physical being. Existentialism focuses on the analysis of human nature, subjectivity, existence, and human finitude in time and space. The analysis of finitude shows that there are different ways of relating to the world, to others, and to God. Human life, existentialists conclude, is *relational* and individuals might be aware of different ways of relating. They do not understand with “relationality” personal relations only, but constitutive relations, which give human beings their identity. It is the capability of relating that differentiates human beings from mere things. Things and objects lack this ability according to existentialists. Things are “givens”; human life is an open possibility, not a fixed thing. Existentialism has several “subgroups” like atheist existentialism, Christian existentialism, and feminist existentialism. Atheist existentialists claim that the clearing of existence/being does not open for God relationship. Christian existentialists like Søren Kierkegaard, Karl Jaspers, Gabriel Marcel, Rudolph Bultmann, Paul Tillich, and Mary Daly claim that God relationship is constitutive for human self-understanding. Feminist existentialists claim that Man has taken the place left by the exit of Father God; the next step in history is to dismantle and to deconstruct the structure that make the master Man possible: the hierarchical ontology with God or Man at the top. The radical vein is an essential part of existentialism.

Existentialists describe and explicate human relationality. They claim that preceding the objectifying relation to things there is the bodily

lifeworld, which we come to know through moods (*stimmung*), passions, choices, actions, and deeds. Existence in time and space is both for Feuerbach and for Merleau-Ponty (1908–1961) bodily existence in the concrete physical universe. According to Heidegger, *existentialia* like care, death, and freedom belong to human lifeworld. The facing of finitude gives birth to anxiety; it shows the presence of anxiety or nothing in human life; in anxiety, the nothingness of human existence shows itself. Anxiety is an expression of the finitude of human existence; as such, it belongs to all *aware* life according to existentialists. In anxiety, the finitude of human existence shows itself, truly to exist is to *ex-ist*. Existence for existentialists is to step out of the nothingness of existence, as it shows itself in anxiety, and it is to give life content, meaning, and direction through choice, decision, and deed (the Latin *ex-ist* means “to step out”). The analysis of finitude does not only show the negativity of existence, but it also shows the possibility of self-transcendence and of living for others: the ethical striving. Early existentialism and recent existentialism express the ethical striving.

Schelling had coined “the horizon of freedom” as a basic feature of human existence: self-determination, that is, choices and deeds through which humans realize their potentials and their belongingness to being, happens in the horizon of freedom, which by definition is in time. The horizon of freedom is the relationship between the now and the future; only the future is the open possibility. Nietzsche (1844–1900) radicalized the time relationship: it is the future that determines the now; the future is the becoming of the now, also expressing the ethical striving. The horizon of freedom is direction to future: human existence is future-oriented and future-directed. In Heidegger, and in later hermeneutics, especially in Dilthey and in Gadamer, horizon becomes crucial as the *horizon of understanding*: human life, and even life in general, is to be understood in the light of the future possibilities and potentials, not only in the light of its past events and happenings. The individual is in time and space; she or he

constantly projects her or his nature onto unknown future, this being the stage of care (*Sorge*); in the situation of projection, the individual is to decide and to choose what she or he is to become through the leap of choice or of faith (Kierkegaard). Choice, through which humans realize and come to consciousness of their selves, happens only in the horizon of freedom according to existentialists. Both in Kierkegaard and in Sartre, freedom is self-communicative, that is, freedom in one person affects and “starts” freedom in the Other; the individual is a part of the human race or human species. Freedom is not “my freedom,” freedom belongs to all; “it” determines the individual and the species. The relationship between the individual and humanity at large or the human species is a central theme in existentialism. In Sartre’s view, there cannot be any realized good or realized and materialized human nature that is not good for all; the individual good enriching the humanity of humans is the only good according to him (Sartre 1946).

Getting inspiration from Heidegger’s analysis of thinghood and of technology, recent existentialism analyses the human predicament in the era of technology and globalization. It warns us of objectifying and rectifying human life; a danger in the present situation is that we understand ourselves as things among things. When the horizon of understanding is determined by the ontology of thinghood, we tend to understand ourselves as things among things; we do not see ourselves as time beings with the continuity between the past, the now, and future. Things, understood in terms of thinghood, have no time relationship. As we understand ourselves as things among things, we have fallen away from our humanity into a nonpersonal “they”; a kind of “thrownness” characterizes the everyday life according to Heidegger. “Thrownness,” “herd” (Nietzsche), “inauthentic living” and “bad faith” (Sartre), and “dreaming innocence” (Kierkegaard) are existentialists’ coinages for living at the mercy of other people. The existential turn at this level is that the individual makes the turning around and starts to look for some more authentic ways of living than just following the stream.

Recent day existentialists claim that the modern scientific perspective, building on the subject/object distinction between the individual and the observed world, gives one perspective on things. Existentialists adhere to perspectivism, Nietzsche being a portal figure in modern, or rather, in postmodern perspectivism. The objectifying relation presupposes that the individual posits her or him as an observer in relation to the world, creating the subject/object structure between the individual and the world. Thinkers profoundly influenced by existentialism, like Martin Buber (1878–1965) and Paul Tillich (1886–1965), consider that the subject/object structure lays the ground of the cognitive relation in modern natural science. In claiming this, they were inspired by Heidegger, Kierkegaard, and Feuerbach. Behind these three, there lies the influence of Fichte (1762–1814). Fichte had opened for human self-determination, and self-determination is a central theme in existentialism. Feuerbach analyzed the possibilities of self-determination and concluded that the subject/object relation between the individual and the observed world or nature is a result of the act of positing. Given the relationality of human existence, this act of self-determination is in Feuerbach’s view a secondary act. Prior to the subject/object relation, there is the I and Thou relation: before the individuals posit themselves as autonomous thinking selves, they are in the world as concrete bodily beings in the company of fellow men and women (Feuerbach 1957). Feuerbach is the initiator both of the I and Thou philosophy and of the existential/phenomenological analysis of bodily/physical being. He was an inspirational source for Nietzsche, and he should be seen as one of the foundational figures of existentialism. Martin Buber developed the I and Thou philosophy and conceptualized the objectifying relation as the I-it relation, setting it apart from the more primordial and original relation of I and Thou. According to Buber, science and scientific knowledge are congruent with the I-it relation; human active self-determination is in the I and Thou relation. It is in relation to the Other that the positing of subjectivity or self-determination

comes to pass according to Buber: only in relation to another Thou the individual finds her or his true “deeper” self. Maurice Merleau-Ponty also held the view that the individual self-determination happens only in relation to the Other: the individual understands who and what she/he is only in the company of other human beings. Christian existentialists emphasize the central role of God relationship in the act of self-determination.

Simone de Beauvoir (1908–1986), living side by side with Jean-Paul Sartre (1905–1980) and also working with him, analyzed the gaze or the look of the Other. Historically, women have been submitted to the look of the Other, which for Beauvoir is the look of man. Under the look of man, or of men, women understand themselves as passive objects instead of taking hold of their innermost capabilities to action and self-determination; authentic living between men and women is to go beyond the objectifying look and the bad faith; it is to understand oneself as an active agent of self-activity and self-determination. In bad faith, coined by Sartre, the human self-understanding is not determined by the individual’s own self-determination and own choice, but by that what the individual believes *others think* of her/him. In the state of bad faith, the individual’s possibilities and potentials have not shown themselves yet, that is, the individual has not come to consciousness. Recent existential theologians, like Mary Daly, emphasize the interactional nature of consciousness: both women and men are in the power of bad faith. If one pole of the interactional setting changes, in Daly’s view women’s consciousness, then the change of the other pole, of men’s consciousness, will follow. Recent day existentialism is moving away from the individualistic interpretations to communal, societal, and interactional interpretations of human being there, seeing individuals as performative agents in interaction and inter-dependence with each other.

Existentialism considers itself as humanism. Sartre had written *Existentialism Is a Humanism* in 1946, Heidegger answered Sartre (who had referred to Heidegger an existentialist, which Heidegger was unwilling to accept) by

composing *Letter on Humanism* in 1947. Sartre had claimed that existence precedes essence: a human being is thrown into existence; she or he has to accept the finitude and anxiety of existence and to understand that it is through her or his choices that she or he makes her or his life and fills existence with content, direction, and meaning. Heidegger’s point in *Letter on Humanism* is that the humanity of humans has been discussed under the domination of old metaphysics and recently under the domination of technology and the ontology of thinghood. Due to those misconceptions, the humanity of humans has not been reached yet, but someday in the future the possibility of human essence will perhaps show itself. Humanism as we know it today is opposed, Heidegger wrote, “because it does not set the *humanitas* of man high enough” (Heidegger 1993).

Existentialism had its heyday in Germany in the beginning of twentieth century, in France, during 1940s and 1950s, in the USA between 1940s and 1970s, in Russia through Dostoevsky, Shestov, and Berdiaev in the end of nineteenth and in the beginning of twentieth century. *The Great Soviet Encyclopedia* from 1979 characterized existentialism as “an irrationalist current in contemporary bourgeois philosophy” (<http://encyclopedia2.thefreedictionary.com/existentialism>, 2012-05-11). Existentialism has been influential in philosophy, in literature, in art, especially painting, in expressionism, and in constructivism. The existentialist turn grounded both phenomenology and hermeneutics. The themes picked up by existentialism has been developed further by feminist thought, cultural analysis, post-structuralism, post-phenomenology, constructivism, and, recently, by epistemological discussions in reflexive or differential monism.

Self-identification

The early existentialists like Schelling, Feuerbach, Kierkegaard, and Nietzsche considered that they were doing science. These philosophers did not deny the objectivity of thought, as we today understand it as representations of the

world out there (correspondence theory of truth), but they claimed that there must be other kinds of truths as well. They were not relativists, but they considered that representations give only surface knowledge of things and humans. It is not representational truths or representational objectivity that we find in existentialism, but *expressive truths* (existential/ontological truth-claims) about the self-to-self and of the mind-reality relation.

Characteristics

The emphasis is on the individual and the description of human finitude with its limits and possibilities are the characteristic features of existentialism. Even if existentialism emphasizes the individual, it also draws attention to the interaction between individuals and between individuals and humanity at large. Further, the action-character of human life is in focus: through action and choice the individuals realize their nature and that realization has impact on other human beings, changing the human nature, and even God's being. Some existentialists like Schelling, Kierkegaard, and Tillich emphasize the change in God: human beings are active agents in an unfinished universe and their actions affect the universe and even enrich God.

Relevance to Science and Religion

Existentialism has drawn attention to the presuppositions and conditions of natural and humanistic sciences: science and scientific truths are of human making and existentialism studies the process of the production of knowledge, the function of knowledge and science in modern society, the value judgments associated with science, representations and "techniques of power" (Foucault) in history and in the contemporary world, the role of prejudices and fore-understandings in human self-understanding. Existentialism has made contribution to the discussion of what science is and what the role of science in the contemporary society is. In existentialism, there has been keen

interest in religion as anthropological, social, and cultural phenomenon. Feuerbach, Kierkegaard, Nietzsche, Dostoevsky, and Berdayev, with Marcel, Jaspers, and Merleau-Ponty, have analyzed religion as a psychological, social, and cultural phenomenon. Nietzsche's cultural philosophy sets many of the main themes of today's cultural analysis.

Sources of Authority

In existentialism, there is skepticism considering authoritative sources; still, the great names of existentialism are considered as authorities. Like empiricism, existentialism listens to the senses, like rationalism existentialism uses reason in the analysis of human existence. But existentialism goes beyond plain empiricism as it claims that an aware mind is more differentiated and alert to life experience than common sense empiricism with its passive camera-view of the mind allows for. Existentialism even goes beyond rationalism in taking hold of the human potential and in claiming that the realization of that potential, the genuine human nature, is the matter of choice and decision, not of rational calculation.

Ethical Principles

Existentialism emphasizes ethical principles like responsibility, reciprocity, action, self-activity, and spiritual development. Existentialism "demands" a respond to human situation subjectively, socially, and culturally. As it sees individuals in interaction with their surroundings, it also presupposes that the individual becomes aware of that how environment and social milieu affect the individual, and how he or she is affecting the surroundings. Reciprocity is that an individual's self-realization happens in relation to other people; reciprocity in the individual-society interaction is to understand the way models of interpretation and patterns of understanding affect the individual, and in what way the individuals contributes to the legitimacy of the

cultural patterns. In existentialism, human nature, that what we are able to become, is dependent on action or choice. Choice, then, is first and foremost an inner act through which the individual strives to become that what he or she is able to become: a self-active, aware, differentiated, and integral self, and this self being a goal of the spiritual development. In Kierkegaard's view, spiritual development gives echo in eternity.

Key Values

The key values of existentialism are affirmation, self-realization, and love. Humans should not shy away from existence, but they should meet existence with open eyes. They should not only affirm themselves as rational beings, but as life-experiencing beings. Life experience is antithetical: there are rational and irrational, good and bad, constructive and negative elements in human existence. The more of the negative one is able to take in and to affirm, the higher the possibility of spiritual development, or the spiritual synthesis of personality. It is love that makes the affirmation possible. Existentialism does not see love as individual property or quality, but love is an existential/ontological matter: individuals partake in love that is in and above them. There is a widespread interest in Spinoza, who also had a participatory view of love. There are existentialists, like Kierkegaard, who identify love and being with each other.

Conceptualization

Nature/World

Nature or world is not only an object of analysis as is the case in natural sciences. Existentialism gives a relational interpretation of the world and or nature: the individual is already in the world, in culture, and in nature. Nature is the sensed, apprehended world.

Human Being

To say what human nature is or to claim that we know what a human being is impossible

according to existentialism. Humans are potential beings: their life is characterized by openness toward future, vulnerability, and unfinished states of affairs (in economy and in personal life). Only future will show what it will become of man. The nonobjectivity of human nature has ethical consequences according to Levinas: to claim that one knows the Other or to claim that we know the human nature is to do violence to the Other. To respect the Other is to let the Other express herself or himself. In these expressions, we only see the exterior of personality, never the core of personality or the seat of underlying motives.

Life and Death

Even if death plays such a central role in existential self-understanding, it shows the finiteness of life to us; existentialism is a philosophy of life. Existentialism puts things in relation to life experience. Death has a this-worldly meaning: it forces us to summon our life and to accept death as a limit of life. Faced with the possibility of death, we are confronting two possibilities: either to escape from death (and from life) or to accept death as a springboard of spiritual growth. It is useless to speculate about life hereafter or about the origins of life, as the origins and the ultimate outcome of life are beyond the reach of human knowledge.

Reality

The complete knowledge of reality is not accessible to human beings. There are perspectives on reality: perspectives in natural sciences give some view on reality; the ethical perspective shows the relationality of life; the perspective of faith gives an understanding of reality. Existentialism affirms that there is a reality independent of human beings, but all knowable reality is in relation to human beings. Human beings express their understanding of reality in art, in science, in philosophy, and in religion. Giving emphasis to action, existentialism pleads for the openness of reality, claiming that the ultimate outcome of reality, whatever that is, is also dependent on human action and choice, not only on the anonymous forces of universe.

Knowledge

There are several kinds of knowledge. The representational knowledge of modern science is one kind of knowledge. Existentialism claims that the representational knowledge or objective knowledge touches only the outer relations of things and humans. The participatory knowledge, on the other hand, is an existential/intuitive form of knowledge. To differentiate between different forms of knowledge is essential to existentialism. Existentialists are attracted by Aristotle's doctrine of informed matter, as Aristotle's differential or reflexive monism comes close to existentialists' understanding of the nature of knowledge, some even claim that Aristotle was an existentialist!

Truth

Most of the existentialists agree with Kierkegaard that subjectivity is the truth: only the personally tested truth-claims have validity, and such truth-claims are approximations to reality. Existentialists think that truth-claims in natural science are also approximations and they consider that scientific truth-claims are dependent on the underlying plane, which has been drawn or projected "in advance." Scientific truth-claims are not final truths as they change over time and have hypothetical character as models. Truth, for an existentialist, is that what gives direction, content, and meaning to one's life; truth and commitment belong together. One "existential" insight into the nature of truth is that error and truth are related, and that there always is the possibility of correcting one's truth-claims.

Perception

It is not the scientific study of perception under the laboratory conditions that is the primary interest of existentialists, but the study of the categories and presets determining perception. The presets are also socially and culturally determined patterns of perception; shortly, the mind is infiltrated by prejudices, evaluations, subjective preferences, and power structures; it is framed by fore-understanding. Existentialists consider that the patterns are historical. Nietzsche's cultural philosophy is the analysis

of the patterns of understanding and of perception: we should be aware of the influence of the patterns of understanding (criticism), but we are also able to introduce new models and new patterns of understanding (construction). With the change in the presets, changed of perception and changed understanding will come; the world is perceived in a new way.

Time

Time is a central category in existentialism. Humans and other living and nonliving things are in time and space. Thinking, feeling, and willing are in time; thinking above time moves in the sphere of abstraction. The existential turn is to turn from abstraction to existence in time and space. Thinking is a matter of coordination of the mind/body totality. The coordination is like navigating the sea, with the difference that the "marks of navigation" mark identity, relationality, and the goal of life. Kierkegaard did the coordination in terms of time. To awaken to consciousness is to become aware of one's past. By telling one's life story consciousness dawns, and one's past becomes a part of the now; one gets an aware relation to one's past, this being an essential part of one's identity. In that very moment, the possibility of future or the futurity of human *dasein* opens itself up as well according to Kierkegaard. Life is continuity between the past, the now, and the future; in repetition the existence that has been becomes in the now (Kierkegaard 1964).

Consciousness

Existentialism gives a relational view of consciousness. Consciousness is not a thing; consciousness is awareness. Consciousness by existentialists is interpreted in several ways. For Sartre (and for Hegel), subjectivity or consciousness is the "I to I": the individual relates to her or him; she or he turns inward and becomes self-conscious. For Kierkegaard, consciousness is a relation to reality outside of the mind. When consciousness or the self comes into being, the "relation relates," he wrote, that is, the aware mind (the "I to I") relates "a third" outside

the mind. The second relation gives the measure of the self, not the “I to I” relation. Only that what is different from the self gives true qualitative difference! Qualitative difference is a sensed difference, and only sensed difference gives consciousness.

Rationality/Reason

Existentialists are not against reason. They are against the exclusive identification of reason with *ratio*. Existentialists do not dismiss reason or rationality, but they are critical of identifying reason or rationality with a second-order phenomena. The second-order phenomena are representations and abstractions and in existentialists view modernity has made a fatal identification between rationality and reason. Reason should be given a much wider definition than *ratio* allows for. Reason might have several interpretations; modernity’s interpretation of reason as procedural reason (Charles Taylor) or as technical reason (Paul Tillich) is a limitation and reduction of reason. The argumentative approach takes arguments as arguments, but arguments are abstractions and as such they are above life, and so is the procedural or technical reason above life as well. For example, in Feuerbach, reason is in life.

Mystery

Some atheist existentialists are open to the mystery of being. Human nature is an enigma; nature and being are groundless; the ground of human life and of knowledge rests on the bottomless abyss. In general, the negative and nothingness are seen as elements of life by existentialists. For Christian existentialists, all created life is finite, and the Christian existentialists look for points of meditation between the finite and the infinite. Like Descartes, some existentialists consider that the relation between the infinite and the finite is internal to the mind; consciousness of finite as finite presupposes the infinite.

Relevant Themes

Existentialism is action oriented. It is in the praxis of life that existential truths are to be

tested. Feminist thought and feminist theology put emphasis on the action and change: through analysis and construction, language, consciousness, and societal structures are changed for a more equal society to take place. Today’s world is characterized by the economization: through globalization all people are affected by economics and macro-political decisions. Existentialism analysis the role of religion, science, and economy in the era of globalization, and it aims to offer constructive alternatives to prevailing economical and political ideologies, emphasizing the local and the initiatives from the below in constructing the condition of livelihood for the individual and for the community. The individual orientation is tuned down in modern existentialism and the interaction between the individual and society, and individual and culture are brought to the foreground.

Interpersonal and institutional processes that have an indirect effect on an individual's well-being even though he/she is not a participant in them; rather, their effects are mediated through interpersonal domains in which the individual does participate. For example, although a child does not participate in the parent's sphere of work or in the meetings of the school board, activities in both of those domains can have consequences in the life of the child. A concept in Bronfenbrenner's ecology of human development.

History

Our access to reality as living organisms is through experience: through our senses, we receive information, and comparing this with what we know, we change our knowledge structure. Aristotle put it this way: *ek tes mnemes empeiria* – out of memory, experience grows. By that, he meant that experience is always a connection of our

sense impressions with already extant knowledge, or in other words, an abstraction from what we perceive into a theoretical structure. During antique times, experience was mainly related to technical knowledge of the artisan and craftsman, like farmers, carpenters, and doctors, who try this and that and finally acquire knowledge about his/her field. Real knowledge, however, was thought to come from reasoning and insight. Aristotle gave a place to empirical knowledge through experience, in his manifold writings about the natural world. In his theory of science, the *Organon*, he acknowledged the role of sense experience in that it fosters the material out of which knowledge is generated. This sense experience which covers singular events, though, has to be brought into relationship with other events and underlying structures, such as causation or correlations have to be abstracted, and this is done by the mind. Finally, these pieces of information have to be put together into a model of what this experience tells us about reality. This is done by what Aristotle calls *anchinoia*, the deep insight of reason, which then uncovers the deep structure of how single events are related. We see smoke. We know that smoke is normally produced by fires. We reason that there must be a fire. In that, we build on our experience around fire: that it is hot, that it burns, and that burning produces smoke. Thus, sense experience and cognitive structures, such as memories and knowledge, are always intertwined.

Middle Ages

During later antique times and the scholastic period of the middle ages, the term used for experience was the Latin verb *experiri* – to make an experience, which is related to traveling. Robert Grosseteste (1168–1253) was the first to use the term systematically to describe his optical experiments. It was more systematically used by Roger Bacon (1218/1219–1292), one of his students. Bacon was the first to postulate a *scientia experimentalis*, an experimental science or a science of experience, which should be the basis for *all* knowledge, even for theology and

philosophy. Since he had no chance to elaborate fully on this, as he was under arrest and could not communicate, we have to glean what he meant by it from the sketches he produced. From that, the following image emerges: Bacon had a holistic view of experience. Inner or spiritual/religious experience and outer experience were two branches of one epistemological access to the world. By spiritual or religious experience, he meant an experience that came out of a contemplative access and illumination received in a kind of mystical rapture. This would give the foundation and general understanding, which could then be used to order the experiences of the outer world through senses and systematic experiments. What Bacon means by inner experiences through raptures is not so different from Aristotle's understanding of *anchinoia*, a clear, direct insight into theoretical structures that serve to connect phenomena we experience in the outer world. It gives us insight about the basic, fundamental principles which we need in order to make sense of experience. For experience itself is not useful unless we can connect it to theoretical structures. And the basic theoretical structures are derived from such insights. For Bacon, such fundamental insights came from spiritual experiences of mystical raptures. In that sense, such inner experiences were spiritual and religious at the same time, as Bacon was a Franciscan friar for whom these experiences could only be given by the God he believed in. What is interesting to see in Bacon is that in this mid-thirteenth-century view, at the cradle of the modern scientific enterprise, the two notions of inner and outer experience are still unified, two facets of one faculty that helps us understand the world. It is not clear whether Bacon had mystical experiences himself, or whether he took his ideas from the abundant Franciscan tradition of ► [spirituality](#), dating back to Saint Francis himself and his close friend Aegidius of Assisi. But he was surely involved in many scientific experiments, probably in the production of gunpowder and other chemical experiments. He advocated studies of medicinal plants, diet, and other regimes to prolong life and to study the effect of large lenses and mirrors to kindle fires, to make optical instruments like telescopes, and so forth.

After him, the scientific efforts to understand the world were gradually intensified. Francis Bacon (1561–1626), who was no relative of the earlier Bacon but used in fact a lot of his writings and took his famous theory of idols from Roger Bacon, advocated experiments to teach us about nature. His ideal was to free us from the bonds that nature, habit, political, and societal convention, as well as current understanding – the idols that bind us – bind us with. The way to do this is to put nature to the test. Here, the language of the judge starts to become pervasive that is still active today, when we speak of controlled *trials*, if we want to test the efficacy of a medical intervention. Francis Bacon saw nature as the one who needs to be tried, submitted, and overcome. He meant that we can reveal nature's secrets by way of experiments. In a parallel movement, Galileo Galilei (1564–1642) actually performed experiments to clarify many notions of mechanics, as did many other contemporary writers and followers after him. During the seventeenth century, it had finally become clear that the high road to understanding nature was to perform experiments. The natural sciences started to form themselves into special disciplines, and experimentation became their way of finding out about the natural world. The outer experience of Roger Bacon had become a methodological stance through the advocacy of Francis Bacon and the example of Galilei. This transformation meant that passive, receptive experience or experience that was the consequence of a journey into unknown lands, literally, had become an active interference with nature. Not only innocent observation, but manipulating nature and not only receptive perception, but interactive experience that resulted from introducing changes into a natural system and observing the result was now the hallmark of scientific experience.

Scientific Experience

Ever since, scientific experience has become a systematic effort of interfering with nature, changing conditions, and observing the effect. A scientific experiment is a precise question put

to nature. The result of the experiment is an answer in the form of a minute piece of experience. It is produced by controlling conditions, where possible, and introducing one changed condition, or sometimes a series of them, to observe the difference. Sometimes, scientific experience is also just about observation, where conditions cannot be manipulated, such as in astronomy. Here, the experiment is the whole cosmos, and scientists use their knowledge to create situations or questions that are similar to real experiments. Sometimes, the experiments are performed by nature herself, such as in biological species that led Darwin to his ► [theory of evolution](#), or in serendipitous observations, as in Jenner's observation that dairymaids who had had cowpox did not contract real pox, or in Fleming's observation that moldy bread could cure some diseases, thereby discovering penicillin. Always, it is the same structure: a defined change is introduced by the scientist into a clearly describable and comparatively controllable system, and the result is observed vis-à-vis an unchanged control condition. Normally, quantitative analysis is used to support the soundness of the conclusions or scrutinize them, although this is not always necessary and rarely is in the large breakthroughs. Thus, experience as a receptive interaction with nature has become a highly structured and highly manipulative interaction.

The original limitation of all our senses has been overcome through the invention of new instruments and methods that extend our senses and aid them into the realms of the infinitely small, the infinitely large, and the infinitely complex. This development had started with the invention of the telescope and the microscope in the sixteenth/seventeenth century, which was already foreshadowed by Roger Bacon's discussions about the power of lenses and reflecting mirrors in the thirteenth century. And it is carrying on today with the construction of huge hadron colliders that allow physicists to peep into the minute constituents of matter and the interface between energy and matter, as well as with the construction of enormous telescopes that allow us to expand our knowledge of the universe. The same is true for instruments such as the electron

microscope or nuclear magnetic resonance spectroscopy that allow us to probe the constituents of more complex structures such as complex biological material up to brain activity.

All these instruments are nothing else but aids for human sense perception which, together with a clever experimental setup, put a question to nature and find the answer. Again, we see the general structure already laid out by Aristotle: sense experience, in the modern case – data, together with memory, in the modern case – theoretical structures, comprises experience.

The Role of Theoretical Structures and Presuppositions

Natural scientists, empiricist philosophers, naïve realists, and positivists often forget about the second part in this equation, the theoretical structures that are necessary to make sense out of the data of sense perception. Nearly everybody in science agrees that data without a theory are useless. The theory, really, has several layers of theoretical structures. The surface structures are normally comparatively innocent, and consensus on them is not difficult to reach. These are current theories that predict certain phenomena that can be empirically tested. Although also here a lot of theory competition prevails, the answers can normally be found empirically and, once found, settle the debate about appropriate theories. For instance, in physics, it was a century-long debate whether light was a particle, as already supposed by Grosseteste, or whether it had to be conceived as a wave. Modern experiments showed that light is both, depending on the setup of the experiment. And a new theoretical structure, quantum mechanics, could also make sense of this double nature. On this level of discourse, science is normally comparatively peaceful and consensus driven, even though the consensus is often only reached through manifold structures of social interactions that are not always rational.

Now, a deeper layer of theoretical structure is often neglected: the preconditions that are supposed to be true and that are needed for any science, whichever kind it is, to proceed and be

able to operate. Such basic theoretical structures are often quietly presupposed and not debated and analyzed further. Various philosophers have pointed to the fact that such preconditions are always operative by necessity. Robin Collingwood called them absolute presuppositions. Pepper called them world hypotheses. Kurt Gödel showed that even the strictest formal system possible, an algebraic formalism, has to make presuppositions that cannot be proven within the system itself; hence, it has to make an assumption. Thomas Kuhn, building on these thinkers, coined the phrase of a “scientific paradigm,” meaning thereby all the hidden, undiscussed assumptions that are taken for granted. Thomas Kuhn had also built on Ludwik Fleck, who had observed that the scientific process of coming to grips with a scientific experience is not just a straightforward matter of data deciding on theories but a highly complex social process. Hence, Fleck coined the phrase: “A scientific fact is the convention to stop thinking.”

These various and similar analyses point to a simple yet deeply unsettling and often neglected fact: all scientific reasoning makes presuppositions that are hardly openly discussed, not necessarily rational and not necessarily true, but the result of a historical process, of societal convention, or just of tradition. Such absolute presuppositions undergird the scientific process. In our modern days, we assume, for instance, that matter is primary and that everything else can be built up from it and that complex processes can be understood in terms of interactions of fundamental building blocks. Our *virtual exchange* particles are no more real or unreal than medieval *intelligences* or *angels* which were a clear consequence of the favored world model then and in the same sense necessary and consistent with the general theory as our “virtual particles” are with modern-day physical theory. The difference certainly is that our modern-day physical worldview is informed by a multitude of empirical knowledge which in turn proves itself useful through the way it is applicable. But the generic theoretical structure is the same: it has to rest on certain assumptions that are not within the scope of the system

itself. In the same sense, it can be imagined that different absolute presuppositions or paradigmatic assumptions might lead to different types of experiences. However, Kuhn and many theoreticians and historians of science have pointed out that such paradigmatic shifts only happen, once the current model has come to a dead end.

We do not discuss and reflect today on how we arrive at such paradigms, world models, or sets of absolute presuppositions that inform our theoretical models and by the same token our experimental work. The consensus opinion today seems to be that such paradigms grow out of the general culture and are historically determined which is to say there is no rational process behind it.

Inner Experience

Here, we turn back to Roger Bacon. In his model of science, the spiritual experience or insight would have provided the basic understanding or structures onto which to build the scientific-experimental enterprise. During his time, however, this strand of thinking was not really taken up. A contemporary of his, the mystical writer Hugh of Balma, a Carthusian (flourished around 1260), even had tried to implement experiential knowledge of God, i.e., spiritual experience derived from a mystical contemplative practice, as a formally accepted way of knowledge into theological learning. However, it remained, as we all know, a sidetrack. Apart from some reverberations – Thomas Aquinas acknowledged it in the final part of his *Theological Sum*, Johannes Gerson, Denys the Carthusian, and his better known friend Nicolaus Cusanus spoke favorably about it – theology remained firmly grounded on its two main pillars: revelation in the scriptures and interpretation through the church and its officials. Direct, experiential, inner experience and knowledge derived thereof did not sit well with the authorities. During the time following Bacon and Hugh of Balma, inner mystical experience became ever more suspect. The council of Vienne 1313, for instance, declared many of the lay groups that advocated such direct access as potentially heretic. The Franciscan fraction of

the spirituals who, following what they felt was Saint Francis' true legacy, also advocated such direct access to inner experience of God, was finally crashed and marginalized. Meister Eckhart (1260–1328), the last of the academic scholastics who might have been in a position to install mystical access to knowledge in an academic environment, was blackmailed and had to defend himself, appealing to the Pope, but dying on his way there. Mysticism had to turn into private piety. It was relegated to religious orders and smaller groups, but was not part of the official, academic structure of acquiring knowledge, which was mainly based on cognitive learning and not on inner experience.

Various reform movements tried to bring this element back into the church. Some were driven out, such as Luther and other figureheads of reformation. Some managed to implement it within the official church, such as Ignatius of Loyola (1491–1556). He developed his own way of inner experience, which he called “spiritual exercises.” Interestingly, directly and indirectly, he had drawn on some of the ideas proposed by Hugh of Balma in the thirteenth century. These exercises are a systematic way of fostering inner, spiritual, and religious experiences and are modeled along the lines of Ignatius' own inner path of experience, which led him through a contemplation of his own shortcomings; the life of Christ in imaginative meditations to an imageless, contemplative presence; and finally, into a deep experience of mystical union which he describes in his autobiography *The Way of the Pilgrim*. Since these exercises became the pillar of the order of Jesuits which Ignatius founded, inner or religious experience came at least indirectly back through some of the teachers who the Jesuits provided at the newly founded schools and universities across Europe and in the New World.

However, this should not disguise the fact that until now, inner, spiritual, or religious experience has not really had a systematic place within our society. And it certainly has had no systematic place in our structures of learning, in the academic world, or in schools. While our culture has invested huge efforts into developing outer

experience of the senses into the systematic tool of science to unravel the secrets of the material universe, we have seen only scattered, unsystematic, often unrelated, and mostly limited efforts at installing a corresponding epistemology of inner experience in our culture. What might such a culture of inner, spiritual, and perhaps, even religious experience look like? What preconditions would it make? What promises and what pitfalls should we be aware of?

If we turn back for a moment to the thirteenth century, when some minds were active to install such a mode of gaining knowledge, inner experience, in our academic system, we see, in a highly sketchy and abbreviated fashion, the following: the medieval psychology had one conceptual tool on offer that might lend itself to an epistemology of inner experience – an inner sense that was directed toward experiencing God directly. It was variably termed *sensus cordis* – the sense of the heart, *sensus interior* – inner sense, *affectus* – affect and its highest part, *scintilla synderesis* – the spark of the synderesis or the spark of the soul, or *apex mentis* – the summit of the mind. All those terms, though used by different writers in different contexts, meant, basically, one thing: there is an organ in the soul whose sole purpose it is to be affected by God and to touch on God. This being touched by God, which in the Christian tradition is of course only possible through grace, was termed mystical union. A case can be made that, although not fully worked out, those writers had an epistemological process in mind which was considered similar and in parallel to the experience of the outer senses: while the outer senses are directed toward the world and bring us knowledge about it in outer experience, the inner sense is directed toward God and brings us knowledge about the deep structure of the world in a kind of inner experience of rapture or enlightenment. This was what Roger Bacon had in mind when he said that such spiritual experience would be the foundation of all sciences, even theology. This was what later writers, such as Hugh of Balma or Meister Eckhart, had in mind when they thought that real wisdom, real knowledge, was derived from such inner experiential insights. As we know, this strand of tradition

was cut short. While we have a comparatively clear epistemology of outer experience in the canon of methods of science, we have practically no understanding of the epistemology of inner experience. This would be a task of the future, should one find the concept useful in the first place.

Various Eastern traditions have placed a lot of emphasis on inner experience, such as the Buddhist tradition and also the tradition of Yoga and Vedanta, the experientially oriented arm of Indian philosophy. They have also derived elaborate bodies of theory about the human mind out of such inner experience. We do not have anything comparable in the West. But we can glean from those traditions that it is possible to elaborate on an epistemology of inner experience.

Epistemology of Inner Experience

While in science proper it is difficult enough to reach consensus about facts of the outer world, which principally speaking can be observed by most people, it seems next to impossible to find consensus about the experiential realities of inner experience. While science has developed clear criteria of correspondence, of testing of truth claims, etc., nothing of the like exists in most religions and only in a few spiritual traditions. Wherever such epistemological methods exist, they are very pragmatic and are about pragmatic consequences. The test then is in the transformatory potential of an experience. In the case of Ignatius of Loyola, he was transformed from a vain knight to a very productive and extremely efficient reformer of the church, inaugurating a clerical order that helped shape the world after him, for better or worse. However, we are very far from a systematic understanding on how such tests would have to be performed and what criteria would be the right ones. Within the Christian tradition, the so-called discernment of spirits is a first step. Here, the criteria of an experience are whether it helps an individual to live his or her life better, whether it sets someone free, whether it helps him or her to be more loving and compassionate, and whether it improves

happiness of more people around the person, to name but a few prominent criteria. But apart from that, not much of a critical epistemology exists.

There is a great danger here, which is not very often recognized: one is tempted to take all content of inner experience at face value. This is also what often happens in modern revivals of spiritual experiences, such as in some strands of transpersonal psychology. How do we know that the voices which Jeanne d'Arc heard were in fact the voices of Saint Michael and Saint Catherine, among others? She was convinced, but what could convince us? There is not much by way of criteria we could use to make such a judgment. She seems to have been in contact with some reality, or her conviction was so strong that she overcame a lot of obstacles; else, she would not have succeeded to help drive back the English from France and eventually help ending the 100 years war. What if someone has an ayahuasca experience and sees the snake god of the jungle? Is this the snake god then? Or just an idle image? What if someone says he or she has seen God, or the Virgin Mary, or Shiva, or Buddha? Do they fantasize? Is it real? Who can tell us? And how do we tell? These problems are unsolved and would be part of the program of an epistemology of inner experience.

They point us to two important problems or distinctions, which we will now turn to: one is the problem of the independent causal agency of consciousness, and one is the problem of language, or the distinction between spiritual and religious experience.

The Status of Inner Experiences

Clearly, inner experience is structurally different from outer, scientific experience of the world in that in inner experience there is no real "sense organ." Rather, the organ of inner experience is consciousness itself. And contrary to outer experience, where we have a comparatively clear referent of a sense experience, say a tree, in inner experience, the referent of an experience is unclear, say the voice of Saint Michael. While science has found some ways round the

ambiguity problem of the outer referent – consensus about what we see, multiple experiments, replication of results, and coherence with other theoretical structures – no such thing exists in the realm of inner experience. If we assume, with mainstream science, that all conscious activity is just derived from and contingent on brain activity, then an inner experience that should be able to tell us something about the outer world as such does not make any conceptual sense. In such a mainstream view, any inner experience can, by definition, only be about the system itself. It can either be the result of such a complex system idling, and it has self-generated meaning and hence devoid of any reference to the outer world. In order to gain ground for inner experience as a real relationship with a reality outside ourselves, we need to presuppose as a minimum precondition that consciousness has some reality and dignity in itself apart from and over and above the fact that it is somehow correlated with brain activity. This does not mean that we are forced to commit to a dualist view. A transcendental monist view would also do. But we need to presuppose that consciousness has its own mode of existence. Then we can craft consciousness and conscious inner experience into a separate mode of access to reality, namely, from the inside. While outer experience teaches us about the world from the outside, inner experience tells us something about its deeper structure if, and only if, consciousness can have its own access to reality in such an inner or spiritual experience. For them, such an experience is really about a transcendent reality that reaches beyond the individual, as is implied by the notion of spiritual experience.

There may be several ways of cultivating such direct access to reality through inner experience – meditation, contemplation, active imagination, shamanic journeys, trance rituals, psychedelic ritual drugs, or other ways of shaping and training consciousness. But they all make the implicit assumption that for consciousness to be in touch with reality by a separate route of inner experience, it has to have its own status of reality apart from being a result of brain activity.

Interpretative Framework of Inner Experiences, Language, and the Distinction Between Spiritual and Religious Experiences

Many scholars have pointed to the fact that experience comes mostly in language structures, and some even say there is no such thing as experience outside and beyond language. This latter claim has been effectively criticized since there are a lot of phenomenological reports about contentless states of consciousness, experiences that were ineffable for a long time until language and meaning structures offered themselves to express those experiences. But by and large at some point, experiences have to be expressed in language if they are to be communicated in some way or another. Even if one only writes the experience down in one's diary for one's own sake and reflection, language has to be used. And even if an experience is painted or transformed into music, some sort of cognitive structure is being used to express the experience.

It is at this interface that spiritual experience is converted into religious experience. We can think of spirituality and religion like the content and the form of a poem. While religion provides the forms – the theological structures, rituals, and mythological narratives – to make sense of experiences, experiences provide religions with the life to carry the rituals and narratives through the ages. If an inner or spiritual experience is interpreted within the framework of a religion, it is called a religious experience. And most religions can be either traced back to deep spiritual experiences, or are direct results of experiences of the founder, such as Buddhism. Although normal religious discourse prefers the term ► [revelation](#), if probed for its real meaning, it is not very difficult to see revelation as a chiffre for the deep spiritual experience of a religion's founder(s). Arguably, this point can be made for historical figures such as Moses and the Jewish prophets, for the historical Jesus and the followers who converted this particular Jewish Rabbi's teaching into a new religion, as well as for Mohammed.

Religious experience then is a subcategory of inner or spiritual experience, namely, that kind of inner experience that fits within and is interpreted by religious language and narratives. It goes without saying that some such experiences also alter the religious narratives themselves as was the case with the experience of the historical Jesus which altered the classical Jewish narrative into what we know today as the Christian narrative. Arguably, such inner experiences can also be interpreted within several frameworks. What Ignatius of Loyola interpreted as a revelation of the Holy Trinity, a modern-day Zen teacher might equate with a Sartori or Kensho experience, saying it has the same quality.

Inner and Outer Experience: Science and Spirituality

Inner experience is the bridge between science and spirituality. We have seen that all science has to rest on theoretical structures and it has to refer back its experiential knowledge to theories that make sense of them. The theories themselves are not found in the data. They are found in and by the mind of great scientists. Normally, this creative process that is at the root of scientific theories is completely neglected. But it is structurally very similar to inner experience: it is sudden insight into a potential theoretical structure that gives meaning. The same is true for spiritual experience: it is the sudden insight into some deep structure of reality, be it in general, or of the reality of one's own life. What is different is the consequence: while in science we then move outward, to looking for further experiential support, in spirituality and religion, these inner experiences normally have consequences for further conduct and behavior, if the experiences were profound. And similar to science, there is the need for distinguishing real experiences and true consequences from fake ones. This is nontrivial, and we have no epistemology to help us. We simply have to assert that inner experience is structurally equivalent to scientific experience,

hence, we only have to practice, meditate, replicate the experience, and that is it, then is in the same way simplistic, inadequate, and positivist as saying: simply observe, do the experiment, and you will know. You will only know what you can see within the framework of the theory you are willing to accept as true. The challenge of inner experience and of scientific creativity is to move us beyond that boundary of the known. Hence, also the framework of religion will ultimately have to be flexible to accommodate such new experience. The same is true for science: if it prohibits certain experiences and decrees certain ways of looking at the world as a priori wrong, then science is not science any longer but scientism, a religion of materialism. It then has the same structure as dogmatic religion. Hence, inner, spiritual experience, or spirituality, and good science are actually very similar. They are both about expanding the horizon of what we know and understand through experience. By the very virtue of this process, they will always modify the theoretical structures that are used to interpret these experiences, whether we call them religion, in the case of inner and spiritual experiences, or science, in the case of outer experience. Ultimately, the driver both of scientific progress and of religious fervor is the same: it is experience of our world, from the inside and the outside that gives us knowledge and insight. John Duns Scotus (1265–1308), the Franciscan scholastic writer and contemporary of Meister Eckhart, puts it in those words: *expertus infallibiliter novit* – who has had an experience has flawless knowledge.

Experiential Philosophy

► Phenomenology

Experimental Philosophy

Bryony Pierce

Department of Philosophy, University of Bristol,
Bristol, UK

Description

Experimental philosophy, or “x-phi,” applies the methods of experimental psychology to the study of intuitions. In a broad sense, experimental philosophy encompasses any work in philosophy or

other disciplines that uses experimental methods with the objective of addressing philosophical questions.

The emblem of the recent experimental philosophy movement is the armchair in flames, which symbolizes a move away from reliance on “armchair philosophy” alone. This movement, which became prominent around the turn of the twenty-first century and is becoming increasingly well established, emerged as a reaction to philosophical practice in the late twentieth century. Philosophy was perceived to have distanced itself from practical experimentation, yet philosophers were making claims thought to be empirical claims, and these were supported only by their own intuitions or those of their associates. Experimental philosophers sought to test some of these claims empirically, or in some cases to investigate questions of their own, using experimental methods rather than relying on some combination of introspection, conceptual analysis, and a priori reasoning.

The 2008 volume, *Experimental Philosophy* (Knobe & Nichols 2008), sets out an “Experimental Philosophy Manifesto,” clarifying experimental philosophy’s aims and explaining how it is a continuation of traditional philosophical practice, rather than a departure from it. Appiah makes the same point in his book, *Experimental Ethics*: “What’s novel isn’t the experimental turn; what’s novel was the turn away from it” (Appiah 2008).

Leading figures in the movement include Joshua Knobe, widely known for his groundbreaking work on intentional action; Thomas Nadelhoffer, coordinator of the *Experimental Philosophy blog* (<http://experimentalphilosophy.typepad.com>); Stephen Stich, who has used cross-cultural studies to challenge the assumptions of traditional analytic philosophy; and Shaun Nichols, coeditor, with Knobe, of *Experimental Philosophy*. Some philosophers were inspired by these researchers or others to use experimental methods; others, in various disciplines, saw a need for empirical studies to investigate philosophical questions, independently of existing work in the field, though often becoming aware of the movement subsequently. The blog

(<http://experimentalphilosophy.typepad.com>) provides details of other leading experimental philosophers, and links to experimental philosophy labs and organizations.

The movement has been viewed as controversial and faces opposition from some, but there is arguably a growing acceptance of experimental philosophy's claim that statements about philosophers' and the folk's intuitions, or about folk concepts, require empirical support, if arguments that appeal to these are to be widely accepted.

Some experimental philosophers identify with the "negative project," also called "experimental restrictivism (or restrictionism)," which seeks to demonstrate that many existing claims are based on suppositions that can be shown to be false. Others are part of the "positive project," which views experimental philosophy's scope as wider and investigates philosophical claims that are considered empirically testable, designing experiments to confirm or refute hypotheses. This distinction is not uncontroversial and is perhaps less relevant in 2011 than in the early years of experimental philosophy.

Research groups holding regular meetings include the Metro Experimental Research Group (MERG, pronounced "merge") in the USA (<http://www.yale.edu/cogsci/MERG.htm>) and the Experimental Philosophy Group UK (<http://sites.google.com/site/experimentalphilosophygroupuk>). There are a number of experimental philosophy labs, an Experimental Philosophy Society (XPS), Facebook groups, an experimental philosophy page (<http://pantheon.yale.edu/~jk762/Experimental-Philosophy.html>), providing links to a wealth of papers and other resources, and an experimental philosophy blog (<http://sites.google.com/site/experimentalphilosophygroupuk>), providing information and a forum for announcements and discussion.

Self-identification

Science

Rather than self-identifying as a science, experimental philosophy is a branch of philosophy that adopts scientific methods in the course of

investigating questions that may or may not be of scientific interest. The philosophical focus of the research carried out in this field is an essential component, so work in this area is never exclusively scientific, but the methods and statistical analysis are expected to meet the same standards as those required in the sciences. Experimental philosophers can be scientists, philosophers, or other nonscientists interested in investigating philosophical questions using experimental methods.

Characteristics

Experimental philosophy is considered a radical departure from standard philosophical methods by those who think that the practice of philosophy necessarily precludes empirical research. It is the only branch of philosophy in which empirical research is viewed as essential and philosophers are involved in investigating empirical questions, often, but not exclusively, through the use of surveys. Other methods include functional neuroimaging, behavioral experiments, and computational modeling. It differs from other contemporaneous types of philosophy in incorporating experimental work. It differs from straightforward scientific research in focusing on philosophical rather than scientific questions, and in attempting to draw philosophical conclusions from experimental results.

Relevance to Science and Religion

Experimental philosophy uses scientific methods in conjunction with the analytic skills of philosophy; it is allied with and dependent upon science, and independent of religion. It can include scientific work or support interdisciplinary work involving the sciences, especially in areas relating to concepts, moral psychology, the mind, or human behavior. It is relevant to and interested in religion only insofar as it sometimes studies attitudes to religion, the effects of religious belief, or intuitions about religious questions.

Sources of Authority

Sources of authority for this subdiscipline have emerged in various forms within the experimental philosophy community. The authority of these sources is not absolute; it derives from their widespread acceptance within the research community. Prominent sources of authority include: *Experimental Philosophy* (Knobe & Nichols 2008)

The Experimental Philosophy Page (<http://pantheon.yale.edu/~jk762/ExperimentalPhilosophy.html>)

The Experimental Philosophy Blog (<http://experimentalphilosophy.typepad.com>)

Other sources would be university research groups, courses and lectures, the experimental philosophy literature, and individual researchers in the field.

Ethical Principles

The main guiding ethical principles are those for any academic research: that work should meet certain criteria or standards, acknowledging sources and recording data accurately, for example. In experimental philosophy, there will normally be an additional requirement that experimental work comply with applicable rules and regulations concerning research on human subjects. Projects involving this kind of research will normally need to be approved by an Ethics Committee (or a representative thereof), and to meet specific criteria stipulated by the academic institution where the research is to be carried out.

Key Values

Key values are the acquisition and dissemination of knowledge, supported by empirical data; methodological rigor (both philosophical and scientific); and the development of theoretical frameworks and testable hypotheses.

Conceptualization

Nature/World

The terms are not explicitly defined within experimental philosophy, although specific conceptions of the world, such as naturalistic versus supernatural world views, are investigated in some experiments.

Human Being

The term is not explicitly defined within experimental philosophy, but a key notion that can be inferred is that of a being with intuitions about the application of concepts, about moral judgments, and about related theoretical positions, which can be investigated by the presentation of hypothetical scenarios.

Life and Death

The terms are not explicitly defined within experimental philosophy.

Reality

The term is not explicitly defined within experimental philosophy, although some thought experiments presented in vignettes may specify a particular version of reality to gauge participants' responses within that context.

Knowledge

There is no fixed definition of this term within experimental philosophy, as a subdiscipline, but folk and philosophers' intuitions about what constitutes knowledge are investigated in some experiments.

Truth

The term is not explicitly defined within experimental philosophy, but folk and philosophers' intuitions about what constitutes truth are investigated in some experiments.

Perception

The term is not explicitly defined within experimental philosophy.

Time

The term is not explicitly defined within experimental philosophy.

Consciousness

The term is not explicitly defined within experimental philosophy, although folk and philosophers' intuitions about consciousness are investigated in some experiments.

Rationality/Reason

The terms are not explicitly defined within experimental philosophy, although the rationality of behavior and folk and philosophers' intuitions about reasons and rationality are investigated in some experiments.

Mystery

The term is not explicitly defined within experimental philosophy.

Relevant Themes

Other topics that are relevant to experimental philosophy's engagement with "Science and Religion" and are critical, in that they constitute a significant proportion of the topics under investigation in the contemporary literature, include:

Intuitions

Concern about assumptions that were made in the philosophical literature about intuitions, whether of the author or attributed to the folk, was instrumental in starting up the experimental philosophy movement, and they are the focus of much of the survey-based work undertaken by experimental philosophers. Scientific work also relies at times on assumptions about what is intuitively obvious and the findings of experimental philosophy could have implications for scientific methodology.

Concepts

Concepts of various kinds have been shown by work in experimental philosophy to diverge, both

within and across different groups. Attempting to discover the nature of folk concepts by conducting surveys is one strategy used by experimental philosophers, either to seek support for positive claims or to demonstrate that certain concepts are incoherent or contingent. Concepts that are applied in some areas of scientific work may need to be revised in the light of this inconsistency.

Action

Many experiments investigate aspects of action, such as when it is conceptualized as intentional, what factors cause particular responses, or the extent to which behavior can be viewed as rational. This work can be interdisciplinary, sometimes with the objective of finding scientific explanations of action or action causation.

Free will

The folk concept of free will has been investigated in the experimental philosophy literature, along with the question of whether the concept is compatibilist or incompatibilist. Related concepts under investigation include agent-causation and moral responsibility. Work in neuroscience has also been undertaken that has implications for theories of freedom of the will.

Morality

Experimental philosophy is interested in moral judgments, how they influence thoughts and behavior, and how they are influenced by other factors. It investigates interactions between moral and other types of judgment, such as judgments about intentions, at the conceptual level, and the effects of different variables on the degree to which people behave morally.

Description

Until quite recently, our conceptions of mind, self, and soul have held these to be internal to the central nervous system of our biological organism, an internal/external boundary which has its roots as far back as the early modern emergence of science. Rejecting both the individual possession and locational internalism of Descartes, there is a growing externalism within scientific and philosophical studies of mind which view it as embodied, enactive, encultured, and interwoven with a social and technical web and as a construction not limited to the boundaries of the individual organism (Wilson 2004). Originating a generation ago in the *content externalism* of Hilary Putnam and Tyler Burge (1986), that the semantic content of mental states is often dependent on factors external to the subject, the last decade has seen the emergence of a substantially stronger *process* or *vehicle externalism*, Andy Clark and David Chalmers' view that the structures or mechanisms making various mental states possible may themselves extend beyond the skin (Clark and Chalmers 1998). Many of our mental states are hybrids, spread across internal and external materials, biological or not. Vehicle externalism can also be rooted in a relational ontology of self, which has implications for a number of religious themes, from the nonduality of enlightened Buddhist views (Rockwell 2005; Thompson 2007) to the Western theological understanding of redemption, which may be better understood as originating in our relational externalities.

Externalism

Externalism is, quite simply, the view that “the mind ain’t in the head.” It is the claim that the mind is constituted by the mechanisms and resources with which we use to think. It asserts that the constitution of thoughts, beliefs, and desires often include, even require, states and processes external to our biological organism. This is not unlike the *extended phenotype* in evolutionary

biology. In the case of human beings, our cognitive niche includes many things by which we extend our minds into the environment, like imitation, symbol use, as well as external artifacts, and even social practices and structures, from which emerge the possibilities of distributing cognitive tasks across individuals or accumulating knowledge across generations. That does not mean that the mind's location is separate from heads and bodies, as these are proper parts of a mind. Mental phenomena are hybrids that couple events in the world to physical processes in the nervous system. According to Mark Rowlands (2003), this is the most important development in the philosophy of mind in the latter half of the twentieth century, rooted in the phenomenological philosophy of Husserl, the linguistic philosophy of Wittgenstein, and the existentialism of Sartre.

The *parity principle* states that “if something plays a role in cognitive activity, such that, were it internal we would have no difficulty in concluding that it was part of the mind, it should be counted as part of the mind whether it is internal or not” (Clark and Chalmers 1998). If Inga and Otto both set out for the Museum of Modern Art, Inga by recalling its location on 53rd Street and the Alzheimer-suffering Otto by consulting his notebook, there is no reason to treat their memories differently, as both are just as accessible, reliable, and transparent in use. Even paradigmatically mental events, like biologically instantiated memory, are not constantly available, not always easily accessible, and not automatically endorsed and can be implicit or procedural. It can also include the downloading to external artifacts which distributes the cognitive load of a task, from paper and pencil to the electronic prostheses of calculators or cell phones.

Parity may only be a special case of a much wider *complementarity principle* which argues, on grounds of both individual differences and historical variations, that the advantages of external resources, both physical and symbolic, might be in *not* merely duplicating internal functions but in developing capacities otherwise unavailable. Different cognitive artifacts do

actually have different effects on our brains, as brain changes in literate populations show and historical and cultural differences in the uses of such artifacts suggest. As Clark (2008) points out, the questions about the range and variety of cognitive scaffolding and the different ways they can enhance (or damage) performance are empirical questions. The nonlinear, complex, and iterated couplings between brain and external resources, in which each may have effects on the other, render any boundary highly permeable, even the extent of context dependence varying widely across contexts and tasks. Such couplings may be precisely what make us the kind of creatures we are, easily extending our minds onto the environment, including the shared social space with which we are so mimetically adept. Indeed, given our extended childhoods, and the extensive shaping of our neuroplasticity during socialization, they make human history and civilization possible.

Internalism

Externalism has been the subject of lengthy controversy, and one can defend a more conventional *internalist* view, that the mind and all properly cognitive processes are contained within the brain. Adams and Aizawa (2008) argue that the “mark of the mental” has other necessary conditions for events to count as cognitive. They must involve *intrinsic content*, and they must be *causally individuated*. A third suggestion is that they must be *informationally integrated*.

Intrinsic content refers by virtue of the *natural* capacities of mental events rather than by *conventional* aspects of human symbols, which must be finally rooted in the natural to avoid an infinite regress. If the meanings of words depend upon the conventions of language, then their externalizations should not count as properly mental states. The problem is that even if this were true, proper mental states are not *limited* to such content, and there are plenty of examples of ordinary thought that *does* use such conventional systems. There are also clear cases of internal representations lacking intrinsic

content, which we do in fact count as mental content. In which case, why not count those which *include* external representations and artifacts.

The requirement of *causal individuation* is that proper mental states must be able to be distinguished in terms of causal regularities, and the set of potential external tools and resources which might be coupled with brains is simply too large and disparate to ever form the object of a science. Unfortunately, this may be one of the very points of contention: Even if *neurological* events and processes can be individuated as a natural kind, this does not entail that mental events can be. Is the mind identical to an entity closed under a relatively low level of causal regularities, if it is not so closed at the functional level of mental states, and their ineliminable intentionalities? Moreover, even putatively internal distinctions, e.g., between automatic and controlled processes, suggest that the mind itself is compounded of more than one natural kind, as are the objects of a number of other sciences.

A third objection is that while certain external supports contain information which guides behavior in the same way that beliefs do, they lack *informational integration*. Beliefs are normally updated holistically, interconnected to a wide network of beliefs. When Inga discovers that my car has broken down, she is likely to also update her belief that I will be driving the carpool tomorrow. An Alzheimer's patient who adds the former belief to a list in a notebook may be surprised when tomorrow's schedule no longer holds. Nevertheless, such integrations also have a time course that can be interrupted, attention which must also be sustained, and connections which are not always made, leaving beliefs with varying degrees of separation. Hence, while this may be a normal characteristic of ordinary beliefs, it is not a necessary one.

Religious and Theological Implications

Teed Rockwell (2005), drawing on the hypothesis of extended cognition, has explicitly endorsed a nondualist model, arguing that even if the brain has enduring substance, the mind itself is

a conventional rather than a natural kind, and there is no sharp border between mind and world. Evan Thompson's Buddhist view is that it is the egocentric attachment to a mentally imputed self that is the source of all suffering, and it suggests ethical practices of empathic imagination, to open oneself to a primary intersubjectivity prior to the imputation of "self" and "other" (Thompson 2007).

There are deep and historical contributions of Christianity to the understanding of interiority as separate, individuated, and bodily restricted and of redemption as a private, individual relationship with the sacred. There are, nevertheless, contemporary theological resources for an externalist view, including Barth's conception of the *imago dei* as existing not in individuals but in relationship itself and Karl Rahner's anti-Platonist view that the substantial unity of the human person is not merely *in praesenti statu vitae* but that we are inescapably wedded to the world. Stanley Grenz's encyclopedic work, *The Social God and the Relational Self* (Grenz 2001), sees a person not as a static entity, determined by its boundaries, but as a drive toward both integration and self-transcendence, and we are ourselves only in communion. What we are *about* is outside ourselves, is *other*. What we *are* even as individual selves are not internal spaces, connected to each other, but literally, and externally, composed of each other.

Faith and Belief

Taede A. Smedes
Faculty of Theology, Radboud University

Related Terms

[Belief](#); [Religious faith](#)

Description

A belief is a mental state (or thought) that has a propositional content (i.e., being either true or false) and which can function as a motivation or justification for someone to behave in accordance with that belief. If John believes that it is going to rain today, this belief explains why he takes an umbrella with him. Beliefs are different from knowledge in the sense that beliefs have the character of being slightly uncertain or provisory (i.e., liable to revision). If I believe I have left my jacket in the garage, I reckon with the situation that my jacket is not in the garage. However, when I go to the garage and find my jacket there, I *know* that I have left it in the garage, and if after having found my jacket in the garage I would say that I still *believe* I have left my jacket in the garage will be taken as silly or as misunderstanding the concept of knowledge.

“Faith,” “belief,” and “religious belief” are sometimes used interchangeably and treated as being synonymous, while in other contexts “faith” and “belief” are seen as opposites. So, e.g., in the cognitive sciences of religion, cognitive scientists and anthropologists are said to study religious belief, where they in fact study the faith – the beliefs and practices – of religious people (Atran 2006). Moreover, many languages have only one word which in some contexts denotes “belief” and in others “faith” (compare the Dutch *geloof* and the German *glaube*).

However, there is a difference in connotation between “faith” and “belief,” where “belief”

refers quite obviously to a propositional content, but where speaking about “faith” emphasizes an attitude of trust and confidence, which can be compared to trust in another human person. Consequently, a belief can be proven false, but this is not the case with faith. For example, someone claiming that “Jesus died around 30 A.D.” is expressing a belief that could be checked in principle and that is either true or false. Someone who says “Jesus Christ is my Lord and Savior” expresses a certain attitude of reverence and worship toward the person of Jesus Christ which cannot be said to be either true or false. Thus a belief can be true or false; faith cannot be said to be true or false but can be sincere, (dis-)honest, deluded, misplaced, and so on.

Faith does, however, presuppose certain beliefs. In both of the aforementioned examples, the person speaking presupposes a belief in the existence or reality of Jesus, although the beliefs in both examples may have different content. In the first case, the person may presuppose the belief in a historical person who died around 30 A.D. In the second case, the person presupposes the belief that Jesus Christ is the historical person who was crucified around 30 A.D. but who is also the risen Son of God. Depending on the faith of the person who makes the second claim, there may be presupposed a whole set of other religious beliefs about the existence and attributes of God, the Trinity, etc., although the person does not have to be conscious of those beliefs at the moment she makes her claim about Jesus Christ.

The difference between faith and belief is sometimes also expressed in terms of “belief that” (belief) and “belief in” (faith). The first expresses propositional content, such as “I believe that two and three makes five.” The second expresses an attitude, such as in the case of “I believe in him,” which may express, e.g., Jane’s conviction that John is capable of writing his first novel. In that case, we say that Jane has faith that John will succeed.

However, often the distinction between faith and belief is not so clear. The philosopher Ludwig Wittgenstein (1889–1951) gives the following example: “Suppose someone were a believer and

said: ‘I believe in a Last Judgment,’ and I said: ‘Well, I’m not so sure. Possibly.’ You would say that there is an enormous gulf between us. If he said ‘There is a German aeroplane overhead,’ and I said ‘Possibly. I’m not so sure,’ you’d say we were fairly near” (Wittgenstein 1978, p. 53). Although at first sight the two claims about the Last Judgment and about the aeroplane overhead have identical grammatical structures and thus may confuse someone, we could say that the first example is a matter of faith, while the second is a matter of belief. We could check in principle whether the aeroplane overhead was of a German type to verify the propositional content of the belief “There is a German aeroplane overhead.” However, someone who believes in the Last Judgment has not simply a belief about the Last Things. Wittgenstein says: “But he has what you might call an unshakeable belief. It will show, not by reasoning or by appeal to ordinary grounds for belief, but rather by regulating for all in his life” (Wittgenstein 1978, p. 54). Believing in the Last Judgment entails an attitude toward one’s entire life, and facts have only limited influence in that they neither verify nor falsify faith.

Another example of the relatedness and difference between belief and faith is John Wisdom’s (1904–1993) parable of the gardener (Wisdom 1951, p. 192 ff.). Two people return to their long neglected garden, and find between the weeds a few of their old plants in very good condition. One of them infers that there must have been a gardener who took care of these plants, whereas the other denies the existence of such a gardener. Both start an elaborate investigation as to the presence and activity of a gardener. As Wisdom (p. 193) emphasizes, “Each learns all the other learns about this and about the garden,” which means that they have equal access to the relevant facts (i.e., the propositional content of their beliefs is identical). But in the end, whereas for the one the faith in the presence and activity of a gardener remains despite the facts, the other believes that there is no gardener because of the facts. The facts are the same, but the attitude of the two persons toward the facts is different.

Although matters of faith and of belief are not often discussed explicitly in literature on science and religion, they are often underlying discussions of religion versus science. For example, creationists believing in the literal truth of the Genesis story have a different attitude toward the confession “I believe in God, Creator of heaven and earth” than other believers. For a creationist, the confession expresses the belief that God is the cause behind the Big Bang and the source of life on earth. This belief can be verified or falsified. The controversy over Darwinian evolutionary theory arises from the underlying belief that evolutionary theory is in direct confrontation with the belief that God is the Creator of life. Creationists thus fear that Darwinian evolution falsifies religious belief. Consequently, strategies have to be found (e.g., Intelligent Design) that falsify Darwinian theory and that prove the plausibility or even the truth of the creationist beliefs.

For many other religious believers, however, the biblical Genesis narrative and the confession “I believe in God, Creator of heaven and earth” is taken to give religious expression to the experience of the contingency of all-that-is, that the entire world ultimately depends for its existence on something (or someone) else that is not created. While the creationist belief may result in an attitude toward science, the second interpretation of the expression results in a faithful attitude toward the world as a whole. Yet, similar to the case of Wittgenstein’s example of the Last Judgment, both creationists and more liberal believers refer to the same expression.

Fallacy

Gonzalo Serrano¹ and Clara H. Sánchez²

¹Department of Philosophy, Universidad Nacional de Colombia, Bogota, Colombia

²Departamento de Matemáticas, Universidad Nacional de Colombia, Bogotá, Colombia

In general, arguments which are faulty or wrong, arguments that seem to be good but have some kind of error, bias, or ambiguity. Fallacies are arguments that transgress either formal rules of logic (against deduction), or some precept of scientific method (against induction, statistics, probability) or some criterion governing dialogue (against good persuasion dialogue). The last kind is known as informal fallacy.

Falsifiability

René Rosfort
Department for Systematic Theology, Faculty of
Theology, University of Copenhagen,
Copenhagen, Denmark

A very influential theory developed by Karl Popper (1902–1994). Only propositions, hypotheses, and theories that can be falsified can be considered scientific. Theories that do not admit of empirical counterexamples have no criteria on which they can be judged true either. Whereas it is easy to find some kind of empirical support for a theory, it remains much more difficult to avoid an empirical contradiction of a theory. Only theories that risk such contradictions can be considered scientific. Theories that put forward claims and arguments that cannot be contradicted remain ungrounded speculations.

Feminism in Judaism

[Jewish feminism](#)

In 1972, a group of ten feminists from New York calling themselves *Ezrat Nashim* (a Hebrew term for the women's section of a traditional synagogue) petitioned the Conservative movement's rabbinical convention, demanding that Jewish women's sexual equality should entail their being subject to the same religious obligations as men. Underpinning this petition for women's full participation in prayer and study was the argument that Jewish women labor under a double social marginalization: that of being Jewish and female, and that masculine values and experiences have alone authorized Judaism's history, religious knowledge, and leadership.

The 1972 petition was but one instance of how the advances won by the Women's Liberation movement and other countercultural forces, in concert with increasing levels of advanced

religious, political, and historical education for women, were being imported into liberal synagogues, consciousness-raising groups, academic curricula, and other fora, by feminist rabbis, historians, theologians, philosophers, artists, and novelists, as well as by women with less public roles in communities all over the world, but especially among well-educated, middle-class Ashkenazi Jews (of central and eastern European origin) in Canada, the United States, and Britain. Since then, resistance to intra-Jewish sexual discrimination has centered on rereading scriptural, halakhic, liturgical, and other classic texts and reclaiming and creating sexually inclusive rituals and rites of passage, as well as vastly expanding historical, sociological, ethnographic, and cultural knowledge of Jewish women's lives. Jewish feminist art and literature's expressive contribution to the reimagining of women's past and future has, from the outset, been central to the project of rendering women the speaking subjects and agents of their own experience.

Because Jewishness also encompasses a culture that exceeds its own religious foundations, not all Jewish feminists are inclined to the reform of Judaism as a religion alone, but focus instead on the ethical, political, and artistic participation of women in a Jewish life that is considered separable from its devotional forms. Indeed, some Jewish feminists repudiate religious observance altogether as being irredeemably incompatible with feminist values, and others still may principally identify as Jewish feminists in solidarity against perceived antisemitism and antisemitic anti-Zionism in the wider women's movement. That being so, Jewish feminism is also unified by a conviction that the full humanity of women is the function of an essentially Jewish universalistic prophetic ethic, not a secular post-Enlightenment one. All Jewish feminists are concerned, to a lesser or greater degree, with the re-narration of Jewish history and the reconceptualization of tradition in ways that recognize women to be agents and resisters, not merely the victims of patriarchy and antisemitism, and as having an evolving, dynamic history of their own that is not always domestic and ancillary to that of men.

But it is important to note that Jewish feminism is not something espoused by women alone. Seldom is it acknowledged that liberal Jewish religious feminism's agenda had already been set by male leaders in the late eighteenth and early nineteenth centuries when the Reform movement, with its spirit of early egalitarianism, sought to make services more spiritually attractive and relevant to women (Meyer 2011). And more immediately, Jewish feminism developed as both praxis and discourse in a postwar context of gendered change affecting men as well as women: not least the traumatization of Jewish masculinity in the Shoah; the emergence of new, more macho, Israeli masculinities, and by the erosion of traditional masculine roles and identities in the wake of the sexual revolution and increasingly disproportionate numbers of women in many liberal congregations and rabbinical training schools. Jewish feminism has also influenced the sexual-political commitments of men in the neo-hasidic pro-feminist ► [Jewish Renewal Movement](#), and among generally non-orthodox male rabbis, some of whom are also gay activists in other Jewish sexual-political arenas.

Jewish feminism is also found among those on the Jewish fringes of neo-paganism, and on the left wing of Modern Orthodoxy. Its influence is felt even among some in Haredi (Ultra-Orthodox) circles, even if, collectively, the Haredim would strenuously deny it. It is, nonetheless, arguable that renewed Haredi insistence on women's traditional maternal and other enabling priorities, as well as ever more stringent requirements for female modesty, has constituted something of a contemporary backlash against the perceived threat of feminist ideas.

The different ways in which feminists use gender as a category of analysis to fund altered and renewed religious practice fall into three main categories. Operating under the Orthodox rubric that Jewish law is divine in origin, and that their gendered difference from men is divinely ordained, Modern Orthodox feminists, such as those within JOFA, the Jewish Orthodox Feminist Alliance, founded by Blu Greenberg in 1997, have sought to adapt Jewish law to better serve women's interests, though only so far as

men (effectively) consider Torah might permit. Since they would consider Judaism to be a practical and social religion before it is a speculative one, the view that Jewish feminist goals will be achieved by halakhic (religio-legal) reform rather than through a revised theology has predominated in these quarters. Orthodox feminism, therefore, tends to focus on specific halakhic problems, such as inequalities in the initiation of divorce; the possibility of developing forms of marriage that are not grounded in *kinyan* (acquisition of the wife by the husband); the requirements of women's *tstnius* (modesty) in dress, and fostering women's religious education, leadership, witness in religious courts, and time-bound ritual observance.

Although hardly indifferent to the rectification of halakhic inequalities, liberal feminists, qua liberals, are far less bound by the rule of law and custom and have been differently preoccupied. Supporting Judith Plaskow's early and well-known claim that the reform of the Jewish theological imaginary must take logical priority over the reformulation of halakhah, the revision of theological language, as well as the language of prayer books toward gender-inclusive or gender-neutral language has typically accompanied efforts to retrieve or create new liturgical sources and theological traditions (e.g., Plaskow 1990; Adler 1998; Raphael 2003). Misogynistic texts and traditions, however canonical their status, are considered to have forfeited their sanctity on those grounds alone. Non-orthodox feminists have also devoted much of their energy to reclaiming rituals considered to have been commandeered by men such as those attending the celebration of the new moon (Rosh Chodesh). Women's *seders*, with the story of liberation from slavery re-narrated in texts written for the occasion by and for women, have also been a social and symbolic focus of Jewish feminist activism since 1976 when the novelist E. M. Broner first held one in her Manhattan apartment, joined by other prominent Jewish feminists of the day such as Gloria Steinem and Bella Abzug, using her own and Naomi Nimrod's *The Women's Haggadah*.

More liberally inclined feminists tend to be of the view that Orthodox feminists can do little more than master a male-governed, masculinist halakhah that has actually made rather few concessions to women. Young Orthodox women, it is widely felt, are not transforming the tradition or learning to speak in their own halakhic voice. In 1998, in her book *Engendering Judaism*, the formerly Orthodox Rachel Adler argued that halakhah should be true to its Hebrew etymological root and take the form of an open-ended path-making, rather than remaining the closed halakhah of patriarchal norms and assumptions. She has not been alone in thinking that when women merely inherit halakhah without changing it they continue to defer to its androcentric narratives and requirements. It is futile for women to attain hermeneutical excellence when such does not methodologically and ethically challenge the texts' existing patriarchal precedents, priorities, and norms.

In her recent response to Adler, Tamar Ross, from an Orthodox Israeli perspective, explained that she cannot subscribe to a Reform commitment to the creation of a (rather than "the") halakhah, because such would fail to acknowledge the divine origin of a tradition that is essentially consensual in character and that derives its power as a cumulative revelation. If Orthodoxy is patriarchal, she claimed, it is not *only* oppressive, but also enables the transmissive continuity of the tradition and preserves the Jewish home and family that is the primary locus of the lived tradition (Ross 2004; Hartman 2007).

With their emphasis on the possibility of historico-ethical progress, liberal types of Jewish feminism are, inevitably, the most historically informed. As Paula Hyman and other Jewish feminist historians have always insisted, reclaiming unrecorded women's histories of leadership, learning, and activism changes the paradigm of what constitutes Jewish tradition and community. Liberal feminists, without any sense that traditional gender roles are divinely ordained by God, are keenly aware of how the antisemitic feminization of Jewish men's otherness has historically complicated the gendering of Jewish identity and practice, or how the history

of modern Jewish identity has tended to overestimate the extent of “assimilation” because it fails to recognize that women’s appointed role as domestic guardians of a family’s Jewishness allowed men to acculturate in public but retain their Jewish identity at home.

Thirdly, and overlapping in some respects with liberal Jewish feminism, there are also types of “postmodern,” post-traditional, Jewish feminism that have rejected what they see as the tendency of both Modern Orthodox and Reform feminisms to foster the kind of sexual equality that renders Jewish women merely honorary Jewish men. Postmodern Jewish feminism, drawing on the radical cultural feminism of the late 1970s and 1980s, as well as elements of contemporary Third Wave feminism, has taken a more eclectic, self-defining direction that is, inevitably, the least concerned about women’s exclusion from a canonical tradition written by and for men. More irreverent in approach, and with a greater willingness to embrace denominational fluidity, ethnic hybridity and queer or nonbinary sexualities, Third Wave Jewish feminists have demoted the classic Second Wave hermeneutic of *a priori* suspicion in favor of one in which a text or observance is not rejected on the assumption of its discriminatory misogyny, but reread for the ambiguities, multivocalities, instabilities, and suppressed possibilities in its construction of gender (Ruttenberg 2001, 2009). This approach, careless of any charge of syncretism or heresy, might therefore include elements of contemporary Goddess feminist spirituality and a vernacularized Jewish mysticism.

In short, the classic Second Wave feminist affirmation of the full humanity and rational, moral and spiritual competence of women has to varying degrees transformed all but the most Orthodox personal and communal Jewish relationships. Women have now joined almost all Jewish learning communities. And although it remains the case that most Jewish women still know traditional Jewish thought and practice from the perspective of canonical texts in which women are the marginal, nonnormative Other, attitudes to women in even relatively traditional communities have seen some quite

dramatic changes in their organizational, ritual, and educational spaces. In the liberal denominations, women’s recently acquired access to advanced religious education has driven liturgical revision and increased opportunities and spaces for women to study Talmud and other classic sources in seminaries and universities toward rabbinic ordination or academic posts in Jewish Studies. But Orthodox women, while excluded from the rabbinate, are also now able to study and teach Talmud in women’s yeshivot (seminaries), with some of them becoming halakhic advisors, though not decisors (*poskim*), particularly with regard to laws governing the intimate aspects of women’s lives, such as menstrual purity. In the United States especially, female cantors and synagogue presidents are now commonly accepted in all but the most conservative congregations. It remains to be seen whether the grandchildren of the Jewish feminists active in the closing decades of the twentieth century will explicitly identify themselves as Jewish feminists, but there is little doubt that Jewish girls’ expectations of their spiritual and intellectual choices and entitlements have been changed irrevocably by the movement.

Feminism in Islam

Miriam Cooke

Asian and Middle East Studies, 203 Franklin Center, Duke University, Durham, NC, USA

Women, Islam, Qur'an, Traditions, Veil, Secularism

In the seventh century, an Arabian trader launched a revolution in social norms that was to shape a faith-based community for 14 centuries. He was the Prophet Muhammad, the first feminist in Islam. In his life and in the revelations that he began to receive in 610 when he was 30 years old, Muhammad became the vehicle for a religion that paid particular attention to the rights of women.

The Qur'an and the Sunna, or the sayings and actions of the Prophet as witnessed by his companions and passed on through the ages, guarantee women life, wealth, and happiness. Before the advent of Islam, female infanticide was a practice among the Arabian tribes. Muhammad forbade it. In a chapter dedicated to women, the Qur'an mandates a woman's right to a dowry and to a half share of inheritance that will remain in her name. Polygyny that was rampant in what has come to be called the Age of Ignorance was severely curtailed. The number of women that a man might marry was reduced to four, and the conditions surrounding the right to marry more than one woman at a time were spelled out. Beyond the first wife, a man might only marry one or more women if they were widows with children. In other words, polygyny

was a form of social security for women whose husbands had died and left them without resources to provide for themselves and their children. Women's rights to happiness in marriage were further protected by a contract that allowed them to stipulate what they expected from their partner. If they did not relish the thought of sharing their man with another woman, they could write such a clause into their contract. Women could demand a man's right to sexual pleasure. Any violation of the contract would liberate them from the bonds of marriage. Women are declared equal with men, created at the same moment out of a single soul, and not wrought out of a man's rib. The introduction of evil into the world is not blamed on a woman, but it is the fault of humanity writ large. Such were the laws sent down from heaven. They were practiced and supplemented in the life of the Prophet.

Muhammad loved women, none more so than his first wife Khadija. She was 15 years his senior and his boss, and it was she who proposed to him. She was the first person to believe in his message and to reassure him that the voice he was hearing was not Satan's but the Angel Gabriel's. His tenderness toward their daughter Fatima was legendary. He did not marry other women until after Khadija's death in 619, and most of the nine women he married were in need. His last and youngest wife Aisha became his greatest confidant, and it is from her that we now have the largest number of traditions that make up the Sunna.

The revolution was betrayed within the first years of the caliphate. The four so-called rightly guided caliphs or successors to the mantle of the Prophet did not follow his lead in caring for the welfare of women. The most noteworthy example can be found right in the heart of the family of the Prophet. Upon the death of her father, Fatima expected to be given her share of the inheritance, but she was denied. Abu Bakr and his entourage claimed that the members of the family were exempt from conditions prevailing for others. When Fatima protested, she was told that her share was to be divided among needy Muslims. Social welfare was invoked to deprive a woman of one of her sacred rights.

That was the beginning of a decline in the moral and social well-being of Muslim women. The swift spread of Islam across Asia and Africa brought Muslims into contact with other cultures and religions that were less solicitous of the rights of women. For the Byzantines, Sassanians, and Jews, women were second-class citizens without basic rights. Whenever possible they were to be kept out of the public eye, expected to devote themselves to domestic duties. When women, especially middle- and upper-class women, ventured out of the house, they were to be shrouded in an all-encompassing garment that indicated their status as possessions of men who could afford to keep their women at home. As Muslims adapted to these new environments, they adopted some of their norms and values. That was how the veil became coded Islamic, the right to knowledge basic to the message of Islam was obfuscated, and the misogynist tradition concerning women's lack in religion and reason was invented.

The manufacture of false traditions, especially ones connected with women, became a cottage industry, and in the ninth century two legal scholars started to clean house. Abu 'Abdallah al-Bukhari and Muslim ibn al-Hajjaj devised a way to distinguish the weak and false traditions from the sound, or *sahih*, ones: "They sifted through 360,000 Traditions to come up with no more than 10,000 sound ones, thereby invalidating 350,000" (S&H, 234).

Their compilations of sound traditions, known as *Sahih Bukhari* and *Sahih Muslim* or *The Two Sounds*, became the unquestionable source for information about the Prophet's life and therefore the sure foundation for the Islamic legal system. Nonetheless, many continued to invoke false traditions and to invent new ones to justify their blatant abuse of women.

Literacy was central to the vouchsafing of women's rights. As long as women were denied education, they remained ignorant of their rights, and men could continue to fashion a world of privilege for themselves. Over time, it was primarily women from the upper classes who learned to read and write and to demand equal opportunities with the men. They were often

members of the rulers' households, like the Valide Sultan or mothers of the Ottoman rulers during the sixteenth and seventeenth centuries. In most cases, their knowledge did not trickle down to the masses, and the oppression of women in Muslim societies became institutionalized.

It was only toward the end of the nineteenth century that middle-class women began to research and assert their rights in Islam. And they did so in tandem with women around the globe. Modernity was marked above all by the visibility of women in public places, and the contact established between Europe and Muslim majority countries emphasized to progressive and conservative Muslims alike the role women should play for a society to be considered modern. The veil and gender segregation came under attack as reformists tried to understand why it was that their societies appeared to be so much less developed than those in Europe. Was the absence of half the population from the public sphere a reason to consider?

Obviously it was, but there was a major problem in answering this question. Women's complaints of gender discrimination seemed to echo the colonizers' criticism of the societies they wanted to control and whose resources they wanted to own. Indeed, the advent of colonialism with its so-called feminist civilizing mission jeopardized the call for women's education and presence in public affairs. Muslim men asserted the need to protect national honor, aka women, from the prying eyes of French, British, and Italian men. At a time when it was clear that women had to play a major role for a society to modernize, the civilizing missions of Europe into Asian and African countries led to a further seclusion of women and renewed insistence on the Islamic imperative of the veil. Women had to be circumspect in articulating any criticism of Islamic norms and values lest their criticism serves the purposes of the enemy.

While it is nineteenth-century male reformists in Lebanon and Egypt who have been recognized for their efforts to change misogynist norms and values, women were also active even if in less

visible ways. The feminist encyclopedist Zaynab Fawwaz and the writers Mayy Ziyada and Aisha Taymuriya were pioneers of a women's movement in the Arab world. In 1892, the first official women's magazine was published in Lebanon, and during the following 30 years, several more women's journals appeared.

The women's press provided space for women to explore the possibilities of participation in the public sphere. Biographies of famous foremothers in Islamic history inspired women to go against convention and to demand the same rights that women at the time of the Prophet Muhammad had enjoyed. He had said that all Muslims should seek knowledge even if it meant that they had to travel as far as China, and these women reiterated his call.

Muslim feminists were careful not to compare themselves with western women. They knew they would be accused of cultural betrayal if they held up colonial societies as being in any way worthy of emulation. Further, colonial leaders had used local men's bad treatment of their women as an excuse to intervene in the private lives of citizens in countries they wanted to dominate. Their superficially feminist position was transparent, and anyone calling for a transformation in gender relations in order to become more western might be suspected of being in collaboration with the outside oppressors.

In the turn of the century, Egypt women began to participate collectively in political culture. In March 1919 Sa'd Zaghlul had asked the British, who were then occupying Egypt, to send an Egyptian delegation, or *wafd*, to Versailles where the Arab world was to be carved into European spheres of control. His request was denied, and he was deported. Immediately, demonstrations were held in many Egyptian towns, and the Wafd Party came into existence. Among the many protests, a "ladies' demonstration" in Cairo hit the headlines. Most of the participants were wives of prominent men, and their leader was Safiyya Zaghlul, Sa'd's wife. Calling themselves "mothers of the nation," women nationalists drew an empowering parallel between family and nation that demanded attention to women's roles in the political arena.

After her husband's departure into exile in 1919, Safiyya continued to hold meetings in their home, the so-called house of the nation. People named her "mother of the Egyptians," and she in turn addressed Egyptians as "devoted sons." Less than a year after the end of World War I, Egyptian women were widely acknowledged to be essential to the success of the anti-colonial struggle (Baron 2005, 135–161). These pioneers foreshadowed the New Woman who did not veil, who did not live in a harem, and whose marriage was not arranged. She was educated and happy in her bourgeois family with a loving husband by her side. When this loving husband died, as did Safiyya's in 1927, the wife was expected to fight for both women's rights and the rights of the nation that were then conflated. To counter this secularized image of the New Woman, the Muslim activist Labiba Ahmad introduced the image of the "new Islamic woman" (190) who took part in society even if behind the veil. Her paper *Al-Nahda al-Nisa'iya* (Women's Awakening) took the lead in promoting the image of a modern, believing woman.

Women were revealing the patriarchal assumptions at the core of nationalist and reform movements whether European and secular or male dominated and Islamic. Founding clubs and associations, they demanded reforms in both religious and civil laws and campaigned for women's rights to education, suffrage, and labor.

In order to dispel doubts and accusations that all they wanted was to become western and secular, some feminists justified their demands using the language and argumentation of Islamic reformers. Concerned not to raise anxiety about their demands for greater equality and visibility, they used family-oriented and socially conservative language. Far from derailing moral norms, their revolution would enhance them and contribute to economic and political progress. Many promoted a modern even if still patriarchal bourgeois nuclear family.

The face veil became inordinately important in the debate over Muslim women's rights, and elite women were at the vanguard of the fight to remove it. By the end of the nineteenth century,

Christian women had generally unveiled, and so the veil acquired a religious meaning when it was Muslim women only who were expected to wear it. Feminists were careful not to link the veil with Islam lest they empower the shaykhs to use counterarguments. Instead, they might couch their opposition to the face veil in physical terms – it was bad for women's health – or in social terms – segregation was bad for society as a whole.

Throughout the twenties, women were testing reactions to unveiling. In 1920, the Syrian Nazik al-'Abid took off her veil in order to fight the French in the battle of Maysoloun. In 1923, Huda Shaarawi, president of the Egyptian Feminist Union, shocked the Muslim world when she stepped off a train in the Cairo railway station with her face uncovered. About the same time in Turkey, the father of the new republic Atatürk launched his secularism campaign with an attack on Islamic symbols, including turbans and veils. In the 1930s the Shah of Iran outlawed the face veil.

Whatever their approaches to women's public assertiveness, there was no denying that a feminist revolution was under way. Technology was transforming the house, and social arrangements in urban arenas were changing as rural migrants used to gender integration moved to the cities.

The feminist revolution, especially against misogynist religious authorities, was underwritten by a widespread attack on religious stagnation and corruption among the shaykhs. In 1926, the blind Egyptian scholar Taha Husayn caused an outcry when he published his autobiography entitled *The Days*. It uncovered corruption pervading religious education. He was harshest on the Azhar scholars who were outraged at such an assault on the central institution of Islamic education.

Muslim women in Asia and Africa began to appear in public their faces uncovered, the upper classes in the Levant and Egypt wearing elegant turbans, flapper dresses, silk stockings, and high heels. Such were the provocations that drove some Syrian shaykhs in the summer of 1927 to pressure the French mandate authorities to order women to veil. Their pronouncement encouraged some zealots to throw acid on women who dared to leave the house unveiled.

Like Egyptian women 8 years earlier, Syrian women took to the streets and a 19-year-old Lebanese Druze named Nazira Zayn al-Din (1908–1976) took to her pen. Citing Qur'an, Sunna, and religious authorities on almost every page, she declared that the veil was not Islamic, but rather a custom. She wrote over 300 pages about the harm to society of covering women's faces and argued for women's equality with men. Within a few months she was done, and in April 1928 she published *Unveiling and Veiling: The Liberation of Woman and the Renewal of the Islamic World*. The second half of the title was a clear salute to Qasim Amin, the Egyptian lawyer who in 1899 had published *The Liberation of Woman*, a book that had caused a stir across the Muslim world (Zayn al-Din 1928/1998, 1929/1998).

In all her writings, Zayn al-Din insisted on the need for *ijtihad*, or independent reasoning, when dealing with matters of faith. Her passionate plea to women to use their minds, to develop individual powers of reasoning, and not to obey blindly the dictates of the shaykhs comes from her readings of reformers like the Iranian Jamal al-Din al-Afghani (1839–1897) and the Egyptian Muhammad 'Abduh (1849–1905), the respected modernist reformers in Egypt who had said that Islam demands the use of reason. They believed that faith without reason was not true faith. Like them, she declared that women's invisibility drags a whole society down and makes it lag behind others that have included women in public space. No society can be just as long as women are not respected and their rights are not protected. That is the universal message she frames in the particular language of the veil and the seclusion of women. The veil is not the sign of lack and inferiority; it is its instrument. *Unveiling and Veiling* created a furor around the world. Letters poured in and the book was reviewed in major journals and newspapers around the world. Some loved it; some hated it. Zayn al-Din collected the letters and reviews and published them the following year in *The Girl and the Shaykhs* (1929).

During the middle decades of the twentieth century, wars of independence from European

rule in Muslim countries, like Algeria, Palestine, and Niger, engaged women as combatants. Some called themselves *mujahidat*, thus linking their action to spiritual and martial struggle in Islam. The importance of women's contributions to national liberation created concern about their power and influence. A backlash ensued similar to the Rosie the Riveter syndrome in post-World War II America.

In the 1960s Muslim women burst on to the literary scene. Writers like the Egyptian Nawal El Saadawi, the Pakistani Qurrat al-Ayn, and the Algerian Assia Djebar wrote angrily about the conditions in which their countrywomen lived. They criticized the male nationalists who did not fulfill their promises of a social revolution in the wake of the colonial expulsions. Another path was chosen by a Muslim sister, called Zaynab al-Ghazali. Closely connected with the Muslim Brothers, she established in 1936 the Association for Muslim Ladies, and 30 years later she found herself in prison with some of the brothers for suspected conspiracy to overthrow the Nasser regime. The memoir that she wrote after her release has all the trappings of a feminist hagiography. She is a saint whose spirituality is so great that she can overcome obstacles like torture that defeat mere men. She attacked Nasser, his regime that was too western and secular for her liking, and even the brothers with her in prison for their weakness and insufficient faith (Cooke 2001).

In this early independence period, women experimented with multiple critiques that allowed them to target the colonizers, the nationalists, the Islamic extremists, and patriarchy without falling into cultural betrayal. The louder these women's voices rose, the more virulent did the Muslim men's responses become. Feminist writings were censured and banned.

The tension between Muslim political extremism and Islamic feminism has grown over the course of the twentieth century. 1979 was a crucial year in this battle. In Iran Ayatollah Khomeini brought an Islamic theocracy to power. Once a bastion of liberal modernity that boasted one of the highest levels of education and skilled employment for women, Iran became

a harsh patriarchy in which women could appear in public only if covered with the black chador. In order to combat the imposition of discriminatory laws in the name of Islam, some Iranian women have been training to become Islamic scholars in women-only seminaries. Others have spoken out against the theocrats and have established transnational feminist coalitions to fight for gender justice at home.

In 1979 also the Pakistani General Zia-ul-Haq promulgated the Hudood Ordinances as part of the Islamization of the country. Hudood included the Zina (or, adultery) Ordinance that criminalizes sex outside marriage with stoning to death as punishment. The "legal definition of zina blurs the lines between adultery [among the married], fornication [among the unmarried] and rape" (Khan 2006, 8). Rape is defined as forced zina, with the burden of proof falling on the woman to produce four witnesses to attest to her violation. If "coercion cannot be proved, the victim becomes an offender who has enjoyed illicit sexual activity" (9). It has been professional women who have opposed the Islamist Jamat-i-Islami and organized resistance against the Zina Ordinance in the name of a well-understood Islam. They are "the daughters and granddaughters of women who participated in the struggle for Pakistan from colonial Britain . . . (who wanted) to expose these laws as having no basis in Islam" (86, 87).

Islamic feminists in Iran, Algeria, Pakistan, Sudan, Yemen, Indonesia, Egypt, and America believe that misogynist laws promulgated in the name of Islam must be resisted, often with arguments articulated within an Islamic paradigm. Some resist individually. The American religious studies scholar Amina Wadud, like Zayn al-Din before her, has been at the forefront of a movement to provide a textual interpretation of the Qur'an from a feminist perspective. Others, like the Revolutionary Association of the Women of Afghanistan and the Pakistani Women Against Fundamentalism, resist collectively by forming associations that advocate Islamic feminist agendas.

In 1982 El Saadawi founded her Arab Women's Solidarity Association with an unveiling agenda: the veil is not merely a piece

of cloth over the face; it is a shroud for the mind. Six years later the government closed the association under pressure from Islamists. Ten years later, infuriated by her continued defiance in books, articles, and interviews, Islamists took El Saadawi to court for apostasy. She won. In 1996 the Revolutionary Association of Women of Afghanistan immediately acted against the misogynist laws the Taliban imposed. More recently, Indonesia, long thought to be a haven for Muslim women, is becoming a battleground for struggles between women and religious extremists.

In their debates with Islamists and others over whether Islam gives women rights to education, work, and control over their bodies, the veil has been central. Turkish and French feminists are fighting their secular governments for the right to cover, while Afghan, Indonesian, and Iraqi women are mobilizing against it and their Islamist regimes. Islamic feminists are uncompromising in their opposition to individuals, institutions, and regimes that claim exclusive authority over their lives and bodies.

Feminist Philosophy of Religion

Erica Appelros

Centre for Theology and Religious Study, Lund University, Lund, Sweden

Description

Feminist philosophers of religion may self-identify with analytic or continental philosophical traditions or combinations thereof and adhere to any one of a multitude of feminist positions. Feminist philosophy of religion does therefore not represent one single philosophical or feminist position. What characterizes feminist philosophy of religion as a discipline in its own right is rather its being a philosophical discipline with religion as its object of study (making it a subdiscipline of philosophy of religion) that employs feminist perspectives and insights in its choice of material, philosophical problems, methods, and theories (thus making it a *feminist* philosophy of religion).

Its emergence as a subject in its own right is fairly recent. For several reasons, feminist philosophical reflections on religion took place within departments of theology and religious studies long before they reached the departments of philosophy where neither religion nor gender was in high priority. Eventually, feminist philosophers began interesting themselves in the subject of religion, in spite of feminism's in general critical stance toward religion, largely identifying religion with patriarchal oppressive systems. Also the need rose within feminist theology for more philosophically stringent work.

Publications from within the emerging specialization feminist philosophy of religion have been increasingly forthcoming since the 1990s. As late as 1994, Nancy Frankenberry could urgently ask "Where are all the feminist philosophers of

religion?" in *Hypatia*, a journal of feminist philosophy (Nancy and Marilyn 1994). The body of literature, self-identified as feminist philosophy of religion, is rapidly growing though, with two monographs tentatively delineating a feminist philosophy of religion, by Pamela Sue Anderson (1998) and Grace Jantzen (1999) (Anderson 1998; Jantzen 1998), a couple of anthologies on the subject (Anderson and Sue 2009; Anderson and Clack 2004), and a growing number of articles on feminist philosophy of religion in collected works and journals of general philosophy, philosophy of religion, feminist and ► [gender](#) studies, and feminist theology. An inclusion of the entry *feminist philosophy of religion* in encyclopedias of philosophy (of religion) is also a sign that the discipline is maturing (Nancy 2005). There is not though yet a journal specifically dedicated to feminist philosophy of religion.

Feminist philosophy of religion currently tries out different avenues in its critical and constructive work, allying itself with and utilizing methods from psychoanalytical or poststructuralist schools, pragmatism, and postcolonialist feminism, among others. What unites the different paths is the emphasis on difference, and that difference matters for how to do philosophy of religion, be it difference in gender, ethnicity, sexual orientation, religion, nationality, class, or age. What also unites feminist philosophers of religion of different standings is an interest in topics such as the concept of God, rationality and epistemology, the human – divine relation, and the relation between humans. The constructive contributions toward these topics are multifaceted, and the critical and deconstructive focus on traditional patriarchal models and presumptions is the same.

Self-identification

Science

In as far as philosophy is considered to be a science, so, consequently, is feminist philosophy of religion. Philosophy is, however, often considered to be more of a metascience, characterized by its analyzing, deconstructive, criticizing, and reconstructive activities, rather than by seeking new knowledge

and discovering new facts, and so, then, consequently, is feminist philosophy of religion.

Religion

Philosophical problems and questions arising from religion as a human phenomenon, with its doctrines, scriptures, rituals, activities, beliefs, language, sociological settings, etc., including the discussion of how to conceptualize religion itself and the divine, are the object of study for the feminist philosopher of religion, who may or may not be religious him/herself. The results from the field of feminist philosophy of religion may of course be useful for theologians in general and for feminist theologians in particular and may shed new light on issues for individual religious believers, but feminist philosophy of religion in itself does in no way self-identify as a religion.

Characteristics

Feminist philosophy of religion is distinctive among other philosophical subdisciplines in its awareness of and focus on feminist and ► [gender](#) issues. Examples include making visible and analyzing women's situations regarding, for instance, power and oppression in language, symbolic and praxis, and introducing philosophical questions and methods originating in women's experiences of, for instance, giving birth, or existing in a marginalized position. While feminist philosophy of religion thus widens the scope of philosophy of religion theoretically, materially, and methodologically, it also questions and deconstructs traditional philosophical presumptions underlying concepts such as rationality, subject, god, knowledge, and objectivity, as being male prejudiced.

Among other feminist academic disciplines, such as feminist theology or gender studies, and among feminist-influenced religious traditions, such as goddess religions, feminist philosophy of religion is distinctive in its strict adherence to philosophical standards of argument and methods of criticism and deconstruction. Its purpose lies in formulating and analyzing philosophical problems arising from a religious context, certainly

suggesting alternative solutions and constructive ideas, but nevertheless leaving matters of application in the religious/theological context to others.

Relevance to Science and Religion

Some feminist philosophers, such as Sandra Harding and Lynn Hankinson Nelson, have analyzed how the methods, models, and underlying worldview of natural sciences are characterized by male language and traditional epistemology, where man is a rational objective subject and nature is an object to be seized and subjugated, a hierarchical relation mirrored in the relation between man and woman, male and female. Feminist philosophy of religion has, in their turn, indicated how these hierarchical models together with religion's likewise hierarchical model of the God-man relation create a destructive potential not only for the male–female relation but also for our environment. This has led feminist philosophers of religion to reconsider the concept of God/the divine and criticize the standard philosophical theistic concept of God.

As feminist philosophy of religion is generally more interested in the implied issues of power and male bias in the existing debates in philosophy of religion than in the debates themselves, this is true also for the debates concerning science and religion, which then become interesting only in as far as they actualize such issues.

Sources of Authority

As feminist philosophy of religion is a fairly new discipline, it still relies heavily on academic works from other disciplines/subdisciplines, in particular continental philosophy (Jacques Derrida, Michel Foucault, Luce Irigaray, and Julie Kristeva), feminist philosophy (Genieve Lloyd, Sandra Harding), feminist and gender studies (Simone de Beauvoir), and feminist theology (Elisabeth Johnson, Daphne Hampson, and Mary Daly). Needless to say, since feminist philosophy of religion does not self-identify as a religion, it does not view religious texts as sources of authority.

Academic works from within the emerging specialization feminist philosophy of religion have been published for scarcely two decades, but the number is growing. As there is not as yet a journal specifically dedicated to feminist philosophy of religion, articles will be dispersed in journals of closely related fields within philosophy, theology, and feminist and gender studies.

Generally, as the discipline is in its forming stage, the more recent a publication is, the more it should have been able to accumulatively further the development of the discipline. More recent publications thus have the potential to become more authoritative than older ones, unless the latter have achieved the status of having become classics within the discipline, as, for instance, Anderson (1998) and Jantzen (1999) presumably have (Anderson 1998; Jantzen 1998).

Ethical Principles

Scholarly work within feminist philosophy of religion is guided by the same general ethical principles as other academic work: it should display intellectual honesty, not succumb to plagiarism, account openly for all material, and give credit where credit belongs.

Key Values

Justice and equality are key values of feminist philosophy of religion and are expressed in the ambition to ensure a fair voice to the marginalized in different contexts, who often are women. Other key values are to stand by sound philosophical principles and methods and to further feminist progress.

Conceptualization

As feminist philosophy of religion is a philosophical discipline where several philosophical schools and traditions are represented, several disparate understandings of the following concepts will coexist within the discipline.

Feminist philosophy of religion will furthermore relate to the following concepts primarily as constituting grounds for philosophical analysis, analyzing their use and the implications and consequences thereof, rather than presenting discipline-specific definitions of the concepts in question. Therefore, the emphasis in the following will be on the philosophical issues actualized by the concepts for feminist philosophers of religion. Some examples will also be given of how feminist philosophers of religion have developed conceptualizations of their own.

Nature/World

Nature/world is significant as a member of a typical Enlightenment hierarchical dichotomy, and nature/culture is mirroring the underlying view that one of the two is more valuable and has power over the other. As culture is viewed as superior to nature, so man is viewed as superior to woman and God as superior to man. Dichotomies such as these and their interdependence are a prime target for the deconstructive activities of feminist philosophy of religion, especially since woman is associated with nature in contrast to man which is associated with culture.

Human Being

Human being understood as a generic male, where the male and the masculine pronoun are taken to unproblematically represent the whole human race, men and women alike, as is often the case in religious and philosophical discourse, is questioned by feminist philosophy of religion, as having far-reaching consequences. Human being as understood as being divided into two distinct separate genders/sexes may also be questioned. The dualistic view of sex and gender predominantly presupposed within religion is, according to feminist philosophy of religion, simplified and does not reflect the more recent developments within feminist theory and medical science. The view of human being as an undivided rational, objective subject/mind, finally, is questioned by foremost continentally influenced feminist philosophy of religion and is replaced with a view of human being as divided, irrational, subjective, bodily, relational, and changing.

Life and Death

The issue of life and death is generating some general discussion within feminist philosophy of religion, though not by way of the traditional interest in life after death. For instance, Grace Jantzen calls attention to traditional religion's focus on death and immortality and argues how/why that might be a result of religion's male origin and dominance. Jantzen suggests, inspired by the psychoanalytic works by Julie Kristeva and Luce Irigaray, that a feminist philosophical understanding of religion should rather promote the love of life and focus on the fact that we are all born, making use of the feminist symbolic of natality (Jantzen 1998).

Reality

For feminist philosophy of religion as influenced by continental and postmodern philosophical thinking, reality is conceptualized as a social and/or linguistic construction. Metaphysical realism is generally criticized, which leads to a potential conflict with the feminist political agenda where realism regarding the real existence of men and women, moral values, and oppressive situations is presumed in order to be able to make claims for changes and reforms. Non- or antirealism, at least with regard to these entities, is for that reason for many feminist philosophers of religion not a viable option. It is not uncommon for feminist philosophers of religion to advocate some kind of critical or pragmatic realism that enables us to speak of a reality and of real injustices, but without having to embrace the problematic God's eye view of metaphysical realism.

Another philosophical issue actualized by the concept of reality is how descriptions and conceptualizations of reality in religion (including God and other religious entities) are colored by their male and patriarchal context and origin, how that in its turn reflects on what we can say or not say about reality apart from human experience, and how women's experience when conceptualized and allowed in to the religious view of ultimate reality will affect it.

Knowledge

The Enlightenment view of knowledge as the product of the isolated rational subject is rejected and instead is emphasized that knowledge is

relational, communal, divided, and multifaceted. Feminist standpoint epistemology is one way, though not the only one, of expressing the thought that what is possible to know depends on where you stand. Those in the margin (often women, poor, or oppressed ethnical or religious groups) have a privileged access to knowledge that those in the center (typically wealthy Western white men) do not have access to. Ramifications of this for religious knowledge and for whose knowledge is counted as authoritative in a religious context are subject to analyze by feminist philosophers of religion.

Truth

Depending on the training and context of the individual feminist philosopher of religion, the conceptualization of truth may differ accordingly, encompassing most current philosophical views of truths. The issue of truth as such is seldom discussed in works of feminist philosophy of religion. See also *reality*.

Perception

Feminist philosophy of religion finds it important to reintroduce the embodied and gendered subject into philosophy of religion and to view sense perception not only as a useful parallel to justify religious experience, as does philosopher of religion William Alston, but as a valuable part of being human and a religious subject, contributing to how theologies are shaped and philosophy of religion is done.

Time

Feminist philosophy of religion is not especially interested in the concept of time.

Consciousness

A well-known feminist concept from feminism's early days in the late 1960s is the concept of consciousness-raising, denoting an activity designed to make women politically conscious of their own oppression. Feminist philosophy of religion often has an implicit or explicit aim to contribute to this consciousness-raising process.

Feminist philosophy of religion is otherwise not especially interested in the concept of consciousness.

Rationality/Reason

One of feminist philosophy's main criticisms of analytic philosophy of religion is its deeply rooted association of rationality/reason with man and maleness and its dichotomy between the rational mind and the sensual body. Feminist philosophy of religion maintains that we cannot separate mind/rationality from the body; as bodily creatures, we need an embodied concept of rationality. Anderson argues specifically that our experiences of desire and yearning must be incorporated into the concept of rationality (Anderson 1998). It is also a matter of concern that rationality has traditionally been viewed as being the property of the isolated rational subject, whereas feminist philosophy of religion emphasizes the role of human relations for rationality.

Mystery

Religion often has a mystic dimension with purportedly ineffable experiences of the divine and is of interest to feminist philosophy of religion only in so far as it actualizes feminist issues. From another point of view, one might say that feminist philosophy of religion revels in the mystery of religion, if mystery is understood as that which analytic rationality cannot grasp, that which dwells in the presymbolic in unarticulated experiences.

Related Terms

[Anatenaria](#); [Religious ritual](#); [Theemithi](#)

Fire-walking is the ► [ritual](#) practice of walking barefoot over fire, hot embers, ashes, or rocks. Accounts of fire-walking are found in early historical records, such as Stabo's descriptions of such rituals in Italy and Cappadocia (*Georgraphy* 5.2.9; 12.2.7). Contemporary fire-walking ► [rituals](#) are performed in many parts of the world, including Greece, Bulgaria, Spain ([Fig. 1](#)), Fiji, South Africa, Paraguay, Sri Lanka, Malaysia, Singapore, Mauritius, the Seychelles, Hawaii, India, Japan, Brazil, Haiti, and Papua New Guinea.

In some cultures, fire-walking is an act of deep religious devotion, such as in the ► [Anastenaria](#) of Greece and Bulgaria, who perform this ► [ritual](#) in honor of saints Helen and Constantine (Danforth 1989; Xygalatas 2012), or the Tamil Hindu festival of ► [Theemithi](#). Participants in such rituals often consider fire-walking as a miracle, claiming that they do not get burned due to divine protection (for a study of a secular fire-walking ritual, see Xygalates et al. 2011). In other cases, most prominently in the USA, fire-walking is part of various New Age movements or performed by professional instructors as a technique for team-building, self-empowerment, fear-control, etc.

However, although it might seem counter-intuitive, it is generally possible to fire-walk unharmed, without any special technique or preparation, physical, mental, or otherwise. The explanation lies in physics: Hardwood, embers, and volcanic rock are very poor conductors of heat. Thus, contact for a short period of time does not usually harm the skin. This is why you do not get burned if you quickly pick up a glowing ember and throw it back into the fireplace. Think of the following example: when baking bread in the oven at high temperatures, you can insert your hand and touch the bread for 1 or 2 s without getting a blister (although you will feel the heat). However, if you touch the metal racks for the same length of time, you will get a blister. The bread and the rack have the same temperature, and, for that matter, so does the air in the oven when you first open it. The reason for not getting burned is that the air and the bread have low thermal conductivity, while the metal rack is an excellent conductor of heat (Leikind and McCarthy 1985). Thus, walking at a normal pace on burning embers is not likely to cause any damage

Fire-Walking, Fig. 1 A fire-walker traversing a coal-bed measured at 677 degrees Celsius (1250 Fahrenheit) while carrying his father on his back, in the Spanish village of San Pedro Manrique

to the feet, although sometimes fire-walkers do get burned, most commonly when an ember gets stuck between their toes, they step on a sharp piece of burning wood, they walk too slowly, etc.

Firewall

Andrew J. Neel
Department of Computer Science,
The University of Memphis, Memphis, TN, USA

A security tool that breaks the normal behavior of data transfers in a way that provides a defense from threats. Firewall examples include application firewalls (breaks data transfers to/from applications where the data is dangerous to the application or its users), network firewalls (firewalls that break high-risk and unauthorized network traffic), and

host firewalls (firewalls that limit applications on desktops, laptops, and servers to behaviors that are explicitly defined or expected).

First Order

Xavier Caicedo

Department of Mathematics, Universidad de los Andes, Bogotá, Colombia

Logical languages that allow atomic predicates and quantification over individuals of the universe only, and not over subsets, predicates, or relations. If the latter is allowed we have second-order logic, and so on.

A first-order structure is a set together with a family of subsets of its Cartesian powers. It may also have distinguished individuals and functions, but these are reducible to relations. Higher-order structures, allowing relations among first-order relations, etc., are reducible to particular first-order structures with an extra binary relation symbol (membership).

Five Pillars

Dustin Byrd

Olivet College, Olivet, MI, USA

The Five Pillars are the basic foundational points in Islam. All five are mandatory for the Muslims

and are the minimal qualifications for what a Muslim is. They are as follows: (1) Shahada, or the “Declaration of Faith,” which states, “I bear witness that there is no god but God, and that Muhammad is his Messenger.” (2) Salat, or the five daily ritual prayers. (3) Zakah, or almsgiving to the poor. (4) Sawm, fasting during the entire month of Ramadan, and (5) Hajj, or the pilgrimage to Mecca in today’s Saudi Arabia.

Fixed Action Pattern

Jörg-Peter Ewert

Faculty of Natural Sciences, University of Kassel, Schauenburg, Germany

According to a classical concept of ethology, a *key stimulus* activates an *innate releasing mechanism* that triggers the adequate *fixed action pattern*. These terms were critically discussed, particularly the prefixes *key*, *innate*, and *fixed*. Fixed action pattern refers to an inherited movement coordination that is characteristic to the species. These movements need not be learned and suggest a genetically fixed ability. “Fixed” misleadingly may denote a rigid and invariable motor performance which, however, has not been observed yet.

Folk Physics

René Rosfort

Department for Systematic Theology, Faculty of Theology, University of Copenhagen, Copenhagen, Denmark

A term for people spontaneously understanding the workings of the physical world. Contrary to scientific physics, folk physics is based on immediate human understanding of the nature of physical objects and intuitive human prediction of physical events in nature. It can be seen as a naïve or common sense approach to human environment. Human interaction with the physical environment is normally based on habits and practical understanding that are very different from the theoretical approach of scientific physics. Thus, insights gained by folk physics are often characterized as contrary to those of scientific physics, and are therefore deemed wrong and misleading with respect to a scientific understanding of the physical world.

Folk Psychology

René Rosfort

Department for Systematic Theology, Faculty of Theology, University of Copenhagen, Copenhagen, Denmark

A term for people intuitively understanding and talking about human psychology. Humans have an immediate understanding of themselves and other people. People behave and talk with other people on the immediate assumption that they generally understand, more or less, how persons

think and feel. Intersubjective relationships are formed and developed by means of folk psychology. When people talk about their mental life, they use words such as “belief,” “idea,” “conviction,” “joy,” “sadness,” “happiness,” and so on. These terms are all part of folk psychology. There is an intense dispute over the status of folk psychology. Some philosophers and cognitive scientists believe folk psychology to be an outdated and ontologically wrong theory of human psychology. We need to substitute the theory with a scientifically more precise theory that can be applied to the physical and biological constitution of the mind. Others contest this as being an expression of a narrow scientific view on human nature. In their eyes, human psychological nature is best explained by means of an elaborated folk psychology.

Description

Forensic medicine is that medical speciality that embraces all medical matters involving the law and all kinds of judicial process. Two main branches exist, clinical forensic medicine, which deals predominantly with the living person and is undertaken by forensic physicians and forensic pathology, undertaken by forensic pathologists which deals predominantly with the dead. Forensic pathology is a branch of pathology concerned with determining the cause of death by examination of a cadaver. The autopsy is performed by the pathologist at the request of a coroner usually during the investigation of criminal law cases and civil law cases in some jurisdictions. [Table 1](#) gives examples of the potential roles for forensic physicians. The training, structure, and delivery of forensic medicine varies around the world, and in some countries both clinical and pathological aspects of forensic medicine are dealt with by the same medical practitioner (Payne-James [2011](#)).

The origins of forensic medicine go back many centuries, although Smith rightly

commented that “forensic medicine [cannot be thought of] as an entity... until a stage of civilization is reached in which we have ... a recognizable legal system ... and an integrated body of medical knowledge and opinion” (Smith [1951](#)).

The specific terms forensic medicine and medical jurisprudence (also referred to as juridical medicine) in the English language date back to the early nineteenth century. In 1840, Thomas Stuart Traill ([1840](#)), referring to the connection between medicine and legislation, stated that “it is known in Germany..... by the name of State Medicine, in Italy and France..... Legal Medicine; [in the United Kingdom] it is usually denominated Medical Jurisprudence or Forensic Medicine.” However, there are many previous references to the use of medical experts to assist the legal process in many other jurisdictions; these physicians would be involved in criminal or civil cases as well as public health. There is much dispute as to when medical expertise in the determination of legal issues was first utilized. In 1975, Chinese archaeologists discovered a number of bamboo pieces dating from about 220 B.C. (Qin dynasty) with rules and regulations for examining injuries inscribed on them. Other historical examples of the link between medicine and the law can be found around the world.

In the Roman Republic, the “Lex Duodecim Tabularum” (laws drafted on 12 tablets and accepted as a single statute in 449 B.C.) had minor references to medicolegal matters, including punishments dependent on the degree of injury caused by an assailant, and poisoning (Brittain). Papyri, related to Roman Egypt, dating from the latter part of the first century to the latter part of the fourth century A.D., contain information about forensic medical examinations or investigations (Amundsen and Ferngren [1978](#)). The “Constitutio Criminalis Carolina,” the code of law published and proclaimed in 1532 in Germany by Emperor Charles V, is considered to have originated Legal Medicine as a specialty: expert medical testimony became a requirement rather than an option in cases of murder, wounding, poisoning, hanging, drowning,

Forensic Medicine, Table 1

Potential roles of a forensic physician

- Determination of fitness to be detained in custody
- Determination of fitness to be released
- Determination of fitness to be charged: competent to understand charge
- Determination of fitness to transfer
- Determination of fitness to be interviewed by the police or detaining body
- Advise that an independent person is required to ensure rights for the vulnerable or mentally disordered
- Assessment of alcohol and drug intoxication and withdrawal
- Comprehensive examination to assess a person's ability to drive a motor vehicle, in general medical terms and related to alcohol and drug misuse
- Undertake intimate body searches for drugs
- Documentation and interpretation of injuries
- Take forensic samples
- Assess and treat personnel injured whilst on duty (e.g., police personnel) including needle stick injuries
- Pronounce life extinct at a scene of death and undertake preliminary advisory role
- Undertake mental state examinations
- Examine adult complainants of serious sexual assault and the alleged perpetrators
- Examine alleged child victims of neglect, physical or sexual abuse
- Examine victims and assailants in alleged police assaults

Additional Roles

- Expert opinion in courts and tribunals
- Death in custody investigation
- Complaints against government officers (e.g., police, security, army)
- Pressure group and independent investigators in ethical and moral issues
 - Victims of torture
 - War crimes
 - Female genital mutilation
- Refugee medicine (medical and forensic issues)
- Asylum seeker medicine (medical and forensic issues)
- Implement principles of immediate management in biological or chemical incidents

For all these examinations a forensic physician must accurately document findings and when needed produce these as written reports for appropriate civil, criminal or other agencies and courts. The forensic physician will be also able to present and interpret the information orally to a court or other tribunal or forum

infanticide, and abortion. Beginning in the latter part of the eighteenth century, a number of books and treatises were published in English concerning forensic medicine and medical jurisprudence. John Gordon Smith writes in 1821 in the Preface to his own book (Smith 1821) “The earliest production in this country, professing to treat of Medical Jurisprudence *generaliter*, was an abstract from a foreign work, comprised in a very small space. It bears the name of “Dr Farr’s Elements, &c and first appeared above thirty years ago.” In fact, it was translated from the 1767 publication *Elemental Medicinae Forensis* by Fazellius of Geneva. Davis (1974) refers to these and to *Remarks on Medical Jurisprudence* by William Dease of Dublin, as well as the *Treatise on Forensic Medicine or Medical Jurisprudence* by O. W. Bartley of Bristol. Davis considers the latter two works of poor quality, stating that the “first original and satisfactory work” was George Male’s *Epitome of Juridical or Forensic Medicine*, published in 1816 (second edition, 1821). Texts on forensic medicine began to appear more rapidly and with much broader content. John Gordon Smith (9) stated in *The Principles of Forensic Medicine Systematically Arranged and Applied to British Practice* (1821) that “Forensic Medicine—Legal, Judiciary or Juridical Medicine—and Medical Jurisprudence are synonymous terms.” Having referred in the Preface to the earlier books, he notes, “It is but justice to mention that the American schools have outstripped us in attention to Forensic Medicine”; he may have been referring to the work of Theodric Romeyn Beck and others. Beck published the first American textbook 2 years later in 1823 and a third (London) edition had been published by 1829 (8). Prior to this, in 1804, J. A. Stringham, who was trained in Edinburgh being awarded an MD in 1799, was appointed as a Professor in Medical Jurisprudence at the College of Physicians and Surgeons of New York and given a Chair in 1813 (11).

Thus, by the end of the nineteenth century, a framework of forensic medicine that persists today had been established in Europe, the UK, America, and related jurisdictions.

The recent growth in awareness of abuses of human rights, torture, disappearances, and civil liberties has directed attention to the conditions of detention of prisoners and to the application of justice to both victim and suspect. Examples of injustice and failure to observe basic human rights or rights enshrined in statute in which the input of medical professionals may be considered, at least, of poor quality and, at worst, criminally negligent have occurred and continue to occur worldwide.

Self-Identification

Science

Forensic medicine is predominantly a science as it is based on medical knowledge. The basic training which underpins forensic medicine derives from a knowledge of anatomy, physiology, biochemistry, and pathology, all scientific disciplines.

Characteristics

Forensic medicine is distinctive from other medical disciplines in that it requires knowledge and understanding related to subjects outside medicine, namely, law and forensic science. Forensic medical practitioners are required to utilize their medical knowledge and interpret it in the context of other nonmedical major disciplines. Additionally, forensic medical practitioners are often faced with moral and ethical decisions related to their professional duties and how they apply those to, for example, complainants, perpetrators, families, employing bodies (e.g., the state), lawyers and judges, without compromising the basic medical duties of consent and confidentiality. The balancing act of duties to the patients and duties to others who may be involved within a legal or judicial process can be complex, but this is part of the day-to-day responsibilities of forensic medicine practitioners.

Relevance to Science and Religion

Forensic medicine is practiced throughout the world and as such works within judicial systems in which religion, culture, and related values may play a greater or lesser part. Thus, medical knowledge may impact on religious issues in implicit or explicit variable ways (e.g., euthanasia, judicial killing) and there may thus be substantial interest by theologians in aspects of forensic medicine and religion.

Sources of Authority

Key sources for medical information should lie predominantly with peer-reviewed studies of randomized, controlled research that have been published and are accessible to all. Forensic medicine, perhaps uniquely among medical disciplines, does not look at how interventions (such as drugs, operations, or procedures) may impact on an individual patient's clinical outcome, but looks at how previous (often nonmedical) interventions, such as stabbing, shooting, sexual assault, drug misuse have affected the person or deceased who is being assessed. There are substantial ethical problems with undertaking research in patient groups assessed by forensic medical practitioners, because of issues of getting true fully informed consent, or in the case of the deceased, consent from families or coroners. Thus, much research is based on historical data. There are however substantial written texts (e.g., *Encyclopedia of Forensic and Legal Medicine*; *Forensic Medicine: Clinical and Pathological Aspects*) that give information on forensic medical issues, and increasing amounts of research are now available and being published which explore clinical issues such as medical findings after sexual assault, and pathological issues such as findings after deaths from drug use. Increasingly sophisticated techniques are being applied, for example, identifying genetic causes for sudden unexplained adult or child deaths.

The majority of peer-reviewed forensic medical journals (e.g., *Journal of Forensic and Legal Medicine*, *Forensic Science International*, *Legal Medicine*, *American Journal of Forensic Medicine and Pathology*) are now also electronically published. Forensic medicine by its very nature links closely with other disciplines such as forensic science, forensic anthropology, and forensic toxicology and there is considerable overlap in the sources of current information. Credibility of such work is dependent on appropriate independent peer review in publications cited in major citation indices (e.g., Pubmed and ISI).

Ethical Principles

The overarching principles of forensic medicine would be generally accepted as the principles espoused by Hippocrates. However, not all doctors take the “Hippocratic Oath.” The principles in general have been enhanced and clarified by both international and national initiatives. An example of the former would be the Declaration of Helsinki. Medical bodies in many countries define how doctors should behave – Table 2 shows the current guidelines for “Good Medical Practice” provided by the General Medical Council that apply to all registered medical practitioners working as doctors in the UK. It will be noted that relationships with and responsibilities to not only patients, but also professional colleagues are explained. It is to be expected that the medical professional organizations in all countries should have published ethical principles to which others can refer.

Key Values

The key values espoused by practitioners or forensic medicine are: (a) to provide appropriate medical care, or interpretation of medical issues within a legal, judicial, or police setting in an independent and unbiased manner –

Forensic Medicine, Table 2 Good medical practice – General Medical Council (United Kingdom – 2006) (the complete documents may be viewed at http://www.gmc-uk.org/guidance/good_medical_practice/index.asp) (Below are reproduced the introductory paragraphs at the time of uniting. Updates are issued on a regular basis)

The duties of a doctor registered with the General Medical Council

Patients must be able to trust doctors with their lives and health. To justify that trust you must show respect for human life and you must:

- Make the care of your patient your first concern
- Protect and promote the health of patients and the public
- Provide a good standard of practice and care
- Keep your professional knowledge and skills up to date
- Recognize and work within the limits of your competence
- Work with colleagues in the ways that best serve patients’ interests
- Treat patients as individuals and respect their dignity
 - Treat patients politely and considerately
 - Respect patients’ right to confidentiality
- Work in partnership with patients
 - Listen to patients and respond to their concerns and preferences
 - Give patients the information they want or need in a way they can understand
 - Respect patients’ right to reach decisions with you about their treatment and care
 - Support patients in caring for themselves to improve and maintain their health
- Be honest and open and act with integrity
 - Act without delay if you have good reason to believe that you or a colleague may be putting patients at risk
 - Never discriminate unfairly against patients or colleagues
 - Never abuse your patients’ trust in you or the public’s trust in the profession

You are personally accountable for your professional practice and must always be prepared to justify your decisions and actions

without allowing personal, religious, moral, or other issues to affect treatment or conclusions, (b) where conflicts occur (e.g., employment status, coercion by authorities) to ensure that duties as a medical practitioner are not compromised, (c) by fulfilling the values in (a) and (b) ensuring that medical issues do not contribute to potential miscarriages of justice.

Conceptualization

It should be emphasized that as forensic medical practitioners are derived from a wide variety of cultures, societies, and religious background, the definitions and concepts of the terms described below will vary according to the individual's personal construct. The comments below are not rigid and may reflect the author's personal interpretations.

Nature/World

The forensic medicine concept of nature and the world is that of the all medical disciplines and reflects striving for a scientific understanding of the world and those that inhabit it.

Human Being

The forensic medical approach to the concept of a human being reflects the belief that humans are sentient and in general are autonomous beings with rights and duties to each other conferred by a variety of moral, ethical, and societal frameworks.

Life and Death

Origins of life are not defined by forensic medical practitioners and will be dependent on their own background. Death can be interpreted and defined in a medical sense by a number of means, which range from brain death with a functioning body, to skeletonized remains. The definitions used will be dependent on the context for which the determination of death is required (e.g., in organ donation).

Reality

Reality reflects that which can be perceived by humans using the sensory and intellectual functions which they possess.

Knowledge

Knowledge is understood to have an objective dimension, such that it is the wisdom that can be transferred in a verbal form from one person to the next, or has been written down in books or libraries. However, knowledge is also understood to have a subjective dimension, which is taken to be the amount of information a person

can retrieve from memory voluntarily, or by being cued.

Truth

Truth as a concept in forensic medicine embodies that which is scientifically correct, and that which may be determined following legal or judicial process, and there may be apparent conflict between the two.

Perception

Perception reflects what is interpreted by an individual from the sensory input supplied to them. In forensic medicine, perception may also be influenced by what others have observed.

Time

Forensic medicine has no particular definition or concept of time beyond that of the ordinary sense. Timing of events may have particular relevance within the forensic medical setting.

Consciousness

Consciousness in the medical sense is the responsiveness of subjects to any external physical or other stimulus. It can vary dependent on many factors including use of drugs, injury, and medical treatment.

Rationality/Reason

Forensic medicine has no particular definition or concept of rationality beyond that used in the ordinary sense. Reason may be applied to events or medical findings in the contexts of observation or perceptions of others, in order to arrive at a conclusion – for example, in the causation of injury.

Mystery

Many would argue that the role of forensic medicine is to assist in solving mysteries.

Relevant Themes

The most important current themes regarding forensic medicine relate to a need for increased

awareness and respect for the living and deceased individual in terms of human rights and medical ethics in the context of duties of doctors. These themes embrace not only healthcare and forensic issues of convicted and nonconvicted detainees in any type of custody, the detection and documentation of torture, appropriate recovery and autopsy processes, but also any setting in which those temporarily or permanently deprived of liberty are in contact with medical practitioners in any setting within legal or judicial process.

Description

Forensic psychology is the application of psychological principles to problems faced by the legal system whereby psychologists intend to help the legal system arrive at fair and unbiased decisions. In a joint publication by the American Psychology and Law Society and the American Academy of Forensic Psychology, forensic psychology is defined as “all professional practice by any psychologist working within any sub-discipline of psychology (e.g., clinical, developmental, cognitive, social) when applying the scientific, technical, or specialized knowledge of psychology to the law” (p. 3) (Ogloff 1999). Some scholars have described the purpose of forensic psychology is to further the cause of social justice in the legal system. Shah, one of the early pioneers in this field, described it eloquently when he wrote, “a basic challenge for psychology in its interactions with legal and social process is to bring relevant knowledge and skill to bear on major social inequities so that the policies and practices in our society can more truly comport with the deepest notions of what is fair and just” (p. 5) (Ogloff 1999).

Historically, research in this field has focused on the topic of eyewitness accuracy. Hugo Munsterberg, who is considered a founding father in forensic psychology, published a seminal piece entitled *On the Witness Stand* (Munsterberg 1908).

Eyewitness research has continued to be important because of the conviction and wrongful imprisonment of innocent persons due to errors in eyewitness testimony (Lindsay et al. 2006; Toglia et al. 2007). The magnitude of the problem was documented by a study that reported 28 cases where DNA testing exonerated the accused; 90 % of the wrongful convictions were due to errors in eyewitness identification (Connors et al. 1996). This is a particularly troublesome result given that research has found that eyewitness memory or identification evidence is perceived to be the most believable evidence that can be offered in a criminal trial (Wells and Bradfield 1998).

The field of forensic psychology has expanded to include direct consultation with attorneys working on both criminal and civil cases. In criminal cases, for example, psychologists may help with determinations of mental status, examination of the quality of the evidence, and assist with jury selection. Civil cases offer psychologists the opportunity to assist with the preparation of a case to maximize jury understanding, determine the impact of events on the long-term psychological status of the plaintiff, and also assist in jury selection among other duties.

Characteristics

Forensic psychology is distinctive because no other subdiscipline of psychology includes as part of its purpose the improvement of legal procedures. While other disciplines may be interested in social justice, forensic psychology is unique in that its practitioners look at social justice issues within the legal system.

Relevance to Science and Religion

Forensic psychology is specifically designed to empirically test assumptions about human psychology that are made by the legal system. Therefore, the issues and questions in this field emerge from a scientific and legal foundation, not a religious one.

Sources of Authority

Forensic psychologists rely on empirical evidence from many areas of psychology to support their work. This empirical evidence is published in stringent peer-reviewed journals that require scientific rigor. Examples of highly respected journals that publish forensic psychology articles include, but are not limited to, *Law and Human Behavior*, *Psychology*, *Public Policy and Law*, *Journal of Experimental Psychology: Applied*, *Behavioral Sciences and the Law*, and *Applied Cognitive Psychology* (Helms 2009).

Ethical Principles

In 1991, the American Academy of Forensic Psychology (AAFP) in conjunction with the American Psychology-Law Society developed a set of ethical principles for forensic psychologists. Those guidelines were published in *Law and Human Behavior* (Committee on Ethical Guidelines for Forensic Psychologists 1991). The Committee on the Revision of the Specialty Guidelines for Forensic Psychology has been revising those guidelines, and the most recent draft, 2008, is awaiting approval (Committee on the Revision of the Specialty Guidelines for Forensic Psychology 2008).

Key Values

The primary value within forensic psychology is to seek the truth about how individuals behave in legal settings. However, because forensic psychology involves a marriage between psychology and law, there are important, fundamental differences between how that occurs in the two disciplines. The legal arena is an adversarial system whereby through cross-examination and presentation of the evidence the truth will emerge. In psychology, the truth is sought through experimentation, observation, and testing hypotheses about human behavior in legal settings. The search for the truth is scientific and not adversarial. The outcome is an

explanation of what and why humans behave the way they do in the legal arena.

Conceptualization

Nature/World

Forensic psychology defines the world in two ways. First, it involves the various settings where forensic psychologists collect information that is used to assist problems faced by the legal system. This would include, for example, the laboratory where psychologists conduct empirical research, or therapeutic settings. The second “world” in forensic psychology is the courtroom or any other legal setting where psychologists attempt to provide information related to problems experienced by those in the legal system.

Human Being

Human being is defined by all of the people involved in the field of psychology and the law from the forensic psychologists who collect information that is presented to the legal system, as well as those in the legal system that are the recipients of that information (judges, lawyers, jurors, defendants, etc.).

Life and Death

In forensic psychology, the terms life and death are very different depending on whether the case is criminal or civil. For instance, in a criminal case that involves the defendant being charged with a crime punishable by death, the trial is held in two parts, the guilt phase and the penalty phase. In the guilt phase, a forensic psychologist may conduct a clinical evaluation to determine whether or not the defendant is competent to stand trial – meaning that he or she is aware of the legal process and can assist his or her lawyers in defending the case, a clinical evaluation to determine the mental status of the defendant, and/or a neurological evaluation to determine whether or not the defendant has brain damage that may impact his or her ability to stand trial. Therefore, a forensic psychologist could participate in several ways during the guilt phase of the trial. If

a defendant is convicted of the crime, then the trial enters the penalty phase whereby the prosecution and defense present additional information to the jury used to determine whether or not to give a penalty of death. During the penalty phase, the prosecution typically has the family of the deceased testify to talk about the pain of their loss in hopes that it will provide justification for the jury to give the death penalty. The defense will use a mitigation specialist, who is typically a forensic psychologist who has done an extensive background analysis of the life of the defendant and can report on “mitigating” circumstances that may help explain the defendant’s behavior. For instance, the mitigation specialist may explain that the defendant came from a very violent and broken home and was physically and sexually abused as a child. The presentation of the mitigating circumstances by the forensic psychologist will be used by the defense attorney to argue that the defendant’s life should be spared.

In a civil case that involves a wrongful death, a forensic psychologist may be employed by the plaintiff to evaluate the family of the deceased. The psychologist would then testify about the psychological injury suffered by the loss of love, affection, and companionship that resulted from the death – a concept referred to in the legal arena as loss of consortium. In many wrongful death cases, the monetary damage award that a jury is allowed to give involves a separate allocation for loss of consortium. Therefore, the way the concept of death and life is viewed by forensic psychologists differs dramatically depending on whether the case is criminal or civil in nature.

Reality

Reality is defined by the observable action of humans in the physical world and the self-reported thoughts they use to describe their motivation for that behavior. From a psychological perspective, reality evolves slowly through the scientific process of collecting and analyzing data and drawing conclusions. In the legal context, reality is the result of an adversarial process whereby both sides present their case to the court.

Knowledge

Forensic psychologists describe knowledge as originating in two forms. Psychologists rely on the evidence from scientific descriptions to create the corpus. The legal system relies on the addition of the logical analysis of the text of the rules developed by cultural institutions, including the previous understanding reflected in precedents.

Truth

Truth is what forensic psychologists seek from conducting empirical research. Truth in the legal system is the result of an adversarial process of both sides presenting their case in court; truth is the outcome of the institutional structures that develop the law.

Perception

Forensic psychologists define perception as the way in which an individual looks at the world as a function of his or her beliefs, attitudes, and experiences. Reality is what we perceive to be true and is often highly individualistic and variable.

Time

Time has multiple meanings to forensic psychologists depending on their subspecialty. Of interest here is how time is measured. For cognitive psychologists who use the concept of time to determine the accuracy of an eyewitness, two critical concepts are related to time. They are (1) exposure duration, the length of time that the witness had to see the perpetrator and (2) retention interval, the amount of time between observing the crime and being presented with the lineup. (3) Additionally, a forensic psychologist may also be interested in reaction time, or the amount of time that an eyewitness took to complete an eyewitness identification task. Each of these three aspects of time (exposure duration, retention interval, and reaction time) is critical to evaluating the accuracy of an eyewitness. Therefore, in terms of estimating or evaluating the memory function of an eyewitness, the concept of time is critical.

Consciousness

There is a great deal of research in human cognition that indicates that much of the information that we observe and process can be done deliberately or consciously with effort, or unconsciously or automatically with little to no effort. Understanding the role of conscious/deliberate or unconscious/automatic processing in the legal arena is vital. Often individuals, like jurors and witnesses, have a poor understanding of their own thought processes and the factors that influence their thoughts. This lack of awareness can lead to biased decision-making and distorted memories. Thus, the role of consciousness is very important to forensic psychologists.

Rationality/Reason

Rationality and reason are defined by forensic psychologists who work on criminal cases which involve understanding the mental processes used by the defendant. As stated earlier, considerable time is spent on understanding mens rea or the psychological status of a defendant at the time the alleged crime took place. Forensic psychologists may be asked to evaluate a defendant and conduct a competency evaluation to determine if the defendant is aware of the charges and can participate in his or her own defense. A battery of mental tests may be given to provide an estimation of the defendant's IQ, ability to engage in mental reasoning, and to determine the source of any mental disease that is detected.

Mystery

A mystery is merely a challenge to resolve the unknown or to clarify information or situations that are difficult to understand. Forensic psychologists seek to remove that which is mysterious by providing empirically or clinically based explanations. However, every forensic psychologist might not arrive at the same conclusion to a given mystery, thus the mystery remains. The problem of not knowing can be transferred from a laboratory to the courtroom, and the mystery can be perpetuated. The problem is that there are many aspects of human behavior that fall outside of scientific understanding that then land in the courtroom and must be evaluated by the trier of fact.

Relevant Themes

Forensic psychology is based on a foundation of science, not religion. However, some of the issues that are examined by forensic psychologists have moral overtones. Perhaps the single most important moral issue in the field involves the question of how society can justify having a legal system that administers the death penalty when it is clear that the system makes mistakes. There are DNA exoneration studies that indicate that many wrongful convictions were based on eyewitness errors, and some involved individuals were convicted of capital crimes and given the death penalty (Huff et al. 1986). It is certainly a moral and to some a religious issue of how can we have a system that invokes the ultimate punishment when it is clear that the system makes mistakes, and under the constitution if a mistake is made, it should favor the accused and not the state. Additionally, how does one further justify the use of the death penalty when it is not distributed equally in states that have the death penalty, as research has demonstrated that demographic factors such as race of defendant, race of the victim, and geographic location impact the likelihood of receiving the death penalty? Additionally, how does society justify having the death penalty in one state and not the other? Therefore, forensic psychologists who study these issues work diligently to do so with an objective eye focusing only on the science, but the outcome of the research certainly has moral, if not ethical, and perhaps even religious connotations that may result in society looking into a mirror and evaluating its own sense of what is right and wrong.

²Departamento de Matemáticas, Universidad Nacional de Colombia, Bogotá, Colombia

The abstract study of deductive arguments. The discipline abstracts from the content of the propositions of the argument the structures or *logical forms* that they embody. For doing this it customarily uses a symbolic *notation* to express such structures clearly and unambiguously and to enable manipulations and tests of validity to be more easily applied.

Description

Can humans have free will when it seems that all events on the macro level of human action are determined by preceding causes (Searle 2007)? The problem of free will is of fundamental importance because many would argue that all human endeavors lose their rationality if humans do not have free will. The aim of this entry is to give an overview of the main positions held in the

English-speaking philosophical discussion of free will over the last 50 years.

What is meant by the term “free will”? Opinions vary, but most philosophers accept that free will implies that an agent being in a decision-making situation can choose between different alternatives, and that she is the cause of her choice so that it was up to her which alternative was chosen. This condition must at least apply to some of our choices, even if not all. As will be shown below, some reject that freedom requires the choice between alternatives, and argue that such a choice can be understood in different ways. The relationship between an agent and her choice can also be understood in different ways.

Most people will say that they experience from their first-person perspective that they have free will. But this experience of having free will seems to be incompatible with both determinism and indeterminism at the macro level of human action. On the one hand, if the world is determined, it seems that everything that happens was determined before our birth, so that no choices are up to us. On the other hand, if indeterminism is part of our choices, it seems to be a matter of chance or luck what we choose, and so again the choice seems not to be up to us. Faced with this problem, some believe that there is no free will. But the *compatibilists* believe that free will is compatible with determinism, and the *libertarians* argue that free will is only compatible with indeterminism. An important question in the debate about free will is hence whether the world is determined or not.

Determinism and Indeterminism

There are many different definitions of “determinism,” but in philosophical discussions of free will today, it is mostly understood as a metaphysical hypothesis referring to the belief that everything that happens necessarily must happen exactly as it does, because of previous causes, so that there is at any time only one possible future. These previous causes may be understood as destiny, God’s predestination, logical necessities, or physical causes, but they all have in common that they determine what will

happen with necessity so that only one future is possible. However, it is physical determinism which is mostly discussed within the philosophy of free will today. Physical determinism means that the laws of nature together with the other basic physical constituents of the world determine one future with physical necessity.

Is the world determined? Determinism has been a very fruitful presupposition for scientists to work with. A common understanding is that Newtonian and relativity physics are deterministic, while quantum mechanics is indeterministic, but this view needs to be nuanced. John Earman shows that there is indeterminism also in Newtonian and relativity physics (Earman 1986). Concerning quantum mechanics, the most common interpretation is the Copenhagen Interpretation and it is indeterministic. But there are also other interpretations, like the deBroglie-Bohm interpretation, which is deterministic.

Most likely we will never know for certain whether or not the world is determined, for there can always be a deeper and unknown level of reality which makes the world at more superficial levels seem either deterministic or not. But in the free will debate focus is on whether our current data support determinism at the macro level of the brain or not. Some, like Max Tegmark, argue that the micro indeterminism of quantum mechanics cancels out at the macro level of the brain. Others, like Stephen Kellert and Henry Stapp, argue that quantum indeterminism at the micro level can be amplified to the macro level of the brain. Yet others, like Roger Penrose and David Hodgson, try to use quantum mechanics to solve the problem of free will by arguing that quantum mechanics can explain first how consciousness arises and then how it gives us free will.

Many remain critical that it would support free will to show that there is indeterminism in the brain. But one should note that there are two very different understandings of indeterminism. One implies a chaotic and random “swerve of atoms” where things happen without causes. But indeterminism need not mean causelessness, but may instead mean that causes are probabilistic. Thus understood, all events have a cause, but they are

not caused with necessity – there is a slight chance that something else might happen instead. It is this kind of indeterminism that libertarians mostly ascribe to (Kane 1996). Critics nevertheless hold that indeterminism makes choices a matter of luck.

Since determinism and indeterminism are important for the free will discussion, this means that other related concepts may also strongly influence how one understands free will. How should one understand the laws of nature or the concept of causality? And what is a human being? Is everything that happens in the human mind the effect of physical causes, or is agent-causation a unique kind of causation which gives humans the ability not to be determined by natural laws and previous physical states of affairs? These questions will not be discussed here, but show that the problem of free will is complex and addresses several disciplines.

There are many positions in the free will debate trying to present a coherent theory of what free will is. Some scholars reject that free will exists, because they believe it is incompatible with either determinism or indeterminism or both. Others again believe that we have free will, but do not understand how it is possible that we do. Other revisions and alternatives also exist, but this entry focuses on the two main positions in the debate: compatibilism and libertarianism.

Compatibilism

The majority of philosophers working with the problem of free will are compatibilists, however in different ways. A first distinction should be made between classical and contemporary compatibilism. The classical compatibilists, like Thomas Hobbes, understood free will as the freedom to do what you want to do. The requirement that one should be “able to do otherwise” they interpreted conditionally in the sense that one “could have done otherwise *if* one had wanted to.” They considered this to be compatible with determinism, because they did not think it important what causes the things we want, only that we are free from constraints when we act.

This understanding should rather be called freedom of *action* (that we can *do* what we

will), but not freedom of *will* (that we can *will* what we will). Harry Frankfurt criticized classical compatibilism (Frankfurt 1971) by arguing that it is also important to take into consideration what causes your willing. For example, it could be that God has decided what your desires and intentions are at every moment of life or that your desires are caused by a machine, an addiction, a phobia, etc. In such cases, you are not free.

Contemporary compatibilists agree that classical compatibilism is no solution to the problem of free will. A trend among these is to reject or redefine what it means to say that freedom requires alternative possibilities. A main argument against the requirement of alternative possibilities comes from the Frankfurt-style examples, originally introduced by Harry Frankfurt: Imagine that someone has full control over your brain, and wants you to perform an evil act. If a prior sign shows that you are about to choose by yourself to do the act, then the control person will not interfere. But if you do not choose to do the act, the control person will manipulate your will in order to make sure you choose and perform the act.

What conclusions can be drawn from the Frankfurt-style examples have been heavily discussed. For if the world is indeterministic, it seems that the evil controller cannot know what the person will choose before she has chosen, but if the world is deterministic, then there were no alternative possibilities anyway. Nevertheless, there is a group of contemporary compatibilists who do not think that having free will and responsibility requires alternative possibilities in the sense that several futures must be possible. The two main positions among contemporary compatibilists are *mesh theories* and *reasons-responsive theories*.

Mesh Theories

Mesh theories claim that a person is free when she has the right connections or “mesh” between internal parts of her mental life. One subcategory is known as hierarchical mesh theories, such as Harry Frankfurt’s and also Gerald Dworkin’s theory. Frankfurt argues that we have several desires whose object is an action or a state,

which he calls first-order desires. But we also have desires whose object is the first-order desire, and these he calls second-order desires. A person may have a first-order desire for drugs, and a second-order desire which either approves or disapproves that first-order desire. According to Frankfurt, we are free when our second-order desires approve our first-order desires, because only then do we have the will we want. Such a mesh between first- and second-order desires is the mesh required for free will.

Frankfurt's theory has been criticized in different ways. For example, it seems that the right mesh can be manipulated into fit by external means, which according to Frankfurt implies that one is free, but this position seems counter-intuitive. Another critique concerns so-called weakness of the will, since it seems we can approve our first-order desires not to smoke, and still smoke. In this case we are not free and responsible Frankfurt maintains, but critics disagree. A third critique is that it is unclear why second-order approval makes it the will of the agent – what is so special with second-order approval if this is as determined as anything else?

There are other kinds of mesh theories besides the hierarchical theories. For example, Gary Watson argues that people are free if their first-order desires are in agreement with their values. Similar critique as that raised against Frankfurt can be raised here: Is the person then not free when acting against her values, or is she free if the agreement has been manipulated? Is the person not free if acting out of weakness of the will? And why are the person's values most important?

Michael Bratman has developed a hierarchical mesh theory which tries to answer much of the critique against Frankfurt, Dworkin, and Watson. Bratman focuses on higher-order intentions and how different desires fit into a larger plan of an agent, and argues that it is the mesh with the greater plan that makes the agent free. These larger plans are created and held over time and give the agent her identity. This means that the agent creates her identity through choices over time, so that one cannot criticize Bratman's theory by saying that an evil scientist could have created the condition that makes the agent free.

But weakness of the will is still a problem in Bratman's theory, since such actions would not count as free in his theory, but intuitively they are.

Reasons-Responsive Theories

Apart from mesh theories, contemporary compatibilists adapt reasons-responsive theories, which hold that a person is free when her actions are based on a rational response to reasons for action. This approach is meant to solve the problem that a correct mesh in mesh theories may have been manipulated, as for example, by way of brainwashing techniques.

Defending such a theory, Susan Wolf argues that one is free when one does the right things for the right reasons, i.e., a person is free when she acts morally good. This theory has been criticized for the problematic consequence that when people act morally bad, they are not free.

A recently much discussed reasons-responsive theory is the semi-compatibilist theory by John Martin Fischer and Mark Ravizza (1998). They agree that the freedom to act on alternative possibilities is incompatible with determinism. But they accept Frankfurt-style examples, believing that freedom with alternative possibilities is not necessary in order to be responsible. Hence, they distinguish between two different types of freedom called *regulative control* and *guidance control*. Regulative control is the strongest type of freedom and includes alternative possibilities. However, Fischer and Ravizza do not believe that humans have such control. Instead, they argue that only guidance control is necessary in order to be responsible, and that this is all the freedom we need: freedom enough to be responsible.

But how can one be responsive to reasons without having alternative possibilities? Is not reason-responding all about being able to do otherwise in different circumstances? Fischer and Ravizza argue that the process that leads an agent to action may include responding to reasons as part of the process even if the agent could not have done otherwise due to, for example, an evil controller as in Frankfurt-style examples. This seems to be correct, but requires that the process

that leads to action is part of or owned by the agent. Critics argue that guidance control is not enough to qualify as free will. Fischer and Ravizza should clarify how the reason-responsive process works and what makes it owned by the agent.

Libertarianism

Libertarians believe that we have free will and that free will is incompatible with determinism. In order to argue that this view is correct, they have both to defend that free will is incompatible with determinism and that the world is not determined. After having rejected compatibilism, they need to show how free will is compatible with indeterminism. A common argument against compatibilism is the *Consequence Argument*, which states, in basic terms, that if determinism is true, then what happens in the future is determined by laws of nature and events that took place in the distant past. Since the future was determined before our birth, it cannot be up to us what happens, and therefore we cannot have free will (Van Inwagen 1983). This argument has been thoroughly debated. Does it follow from determinism that we cannot change the future even if we cannot change the past and the laws of nature? And can a person still be the cause of an action at one level of description even if the Big Bang and the laws of nature are the causes of the same action at another level of description? Despite criticism, the Consequence Argument is still a main reason for libertarians to reject compatibilism.

In addition to defending indeterminism and incompatibilism, the greatest challenge for libertarians is the intelligibility question – to give a positive account of how free will is possible in an indeterministic world. The problem for libertarians is that in the case of indeterminism, it seems to be a matter of chance whether an event occurs or not. But as chance events are not under control of an agent, can then an action be free and responsible? It is important to recall that there are two quite different understandings of indeterminism, and libertarians defend the kind which does not preclude that events can be caused. Nevertheless, libertarian theories are

commonly criticized for making choices a matter of luck.

Different strands of libertarianism can be classified according to how its proponents think actions are caused. *Non-causalists* believe that free actions are not caused at all, but intelligible in light of the purpose of the action. *Agent-causalists* believe that there is a unique and irreducible kind of causation that only free agents can employ. *Event-causalists* reject that actions have special causes, but believe instead that all causes are of the same kind. They argue that events cause events, both in the mind and in the world in general. These views will now be presented and criticized.

Non-causalism

Non-causalists like Carl Ginet believe that actions are not caused at all. Agency is a kind of event different from how other events in the world are caused. Human action can be explained by intentions instead of causes, and these are totally different things. A classic charge against such a view derives from Donald Davidson (1963). He pointed out that even if a person has a reason for doing something, this does not mean that his reason is what actually led the event to happen. There often are several reasons pointing in different directions in the course of acting. The challenge to non-causalists is to explain what links the personal reason to the action.

Agent-Causalism

Agent-causalists like Timothy O'Connor and the early Randolph Clarke hold that agents are enduring irreducible substances who have a unique ability to cause actions. This line of thinking does not have to imply substance dualism, even though, for example, Richard Swinburne is a substance dualist and agent-causalist. A substance dualist view is that it is the soul that chooses among undetermined options. But one may as well conceive of the agent as emerging from physical parts, as long as the agent is understood as an irreducible entity different from the sum of its physical parts.

When agent-causalists explain action, they refer to the reasons the agent has for choosing

one action. A similar critique as raised against non-causalists is relevant here as well, namely the problem of explaining how the reason makes an action happen. Persons often have some reasons for doing A and other reasons for not doing A at the same time, so what is it that makes a reason actually lead to action? Agent-causalists are typically criticized both for appealing to a mysterious agent and a mysterious form of causation, and for not explaining how reasons can make actions happen.

Event-Causalism

Event-causalists hold that mental events can cause free actions. Different opinions on how this happens can be sorted according to when in the deliberation process indeterminism occurs. The advocates of *centered* event-causal theories believe that there is indeterminism until and in the moment of choice (e.g., Robert Kane 1996). The advocates of the *deliberative* event-causal theories hold that there is indeterminism early in the deliberation process creating different ideas in the mind (alternative possibilities), but that the rest of the deliberation process is determined (e.g., the two-stage model of Bob Doyle, inspired by Daniel Dennett and Alfred Mele).

The luck-objection is the most common objection against centered event-causal theories. Let us say there is a 70 % probability that Jack will decide to have pancakes for breakfast. If history had been rolled back a hundred times and played again up to the moment of choice, it seems that Jack would decide to have pancakes 70 times and not 30 times. But if the exact same history up to the moment of choice can give completely different choices, it seems to be a matter of luck what Jack decides to do. The same point can be made with identical worlds up to the moment of choice, where Jack1 and Jack2 make different choices.

Deliberative event-causal theories are meant to evade this problem by moving the indeterminism to an earlier point in the deliberation process. But if what happens at the first stage is undetermined and outside of the agent's control, and then everything is determined at the second stage, the choice still seems outside of the agent's control, and a matter of luck.

Free Will and Neuroscience

Neuroscientists do not generally participate in the philosophical discussion of free will, so when they do speak of free will, it is often ambiguous which sense of "free will" they refer to. However, the neurosciences have brought forth important data and experiments that the philosophers need to take into account. In particular, two kinds of findings are often mentioned. The first is data which suggest that the brain determines what a person does before the person is conscious of having a desire and making a choice. The second is data which suggest that persons do not know the real causes of their actions, but invent a false reason which they believe was their actual reason for action.

As regards the first kind of data, the most famous experiments were done by Benjamin Libet in 1983 and later. His experiments showed that what participants reported as free voluntary acts were preceded by a specific electrical charge beginning 550 ms before the act, while they reported being conscious of their desire to act 350–400 ms after this. Since that leaves around 200 ms before the motoric act, Libet concluded that free will was not disproved since the subjects could still veto the act before it started (Libet et al. 1999).

Libet's experiments have been criticized on many points by philosophers like Alfred Mele. Firstly, the participants were given an assignment where they consciously chose to prepare to flex, so consciousness is already involved in the process. Secondly, the act in question was to flex a finger whenever they wanted. Since this is a choice which does not matter to people, it is hard to conclude from such indifferent choices that the same applies to other choices. Thirdly, the machines only registered when persons flexed, so we do not know if the same electric charge was present when the persons did not flex. Fourthly, the participants flexed when they felt an urge, and Libet uses terms like "intention," "urge," "wanting," "decision," "will," and "wish" as imprecise terms for this desire to move the finger, whereas Mele thinks that there is a great difference between an urge and a decision. Fifthly, the test only applies to choices

to do something now, not to choices to do something later.

Even if it is difficult to draw general conclusions from Libet's experiments, it seems likely that there are nonconscious predecessors to at least some of our choices. Chun Siong Soon et al. set up an experiment similar to Libet's, but designed to counter some of the criticism of his test method. They wanted to investigate more what happens in the brain before making more complicated choices than in the Libet experiment. A group of subjects were asked to press either a left or a right button when they wanted to. At the same time they were shown a slide show of letters K, T, D, etc., in random order. They were asked to note which letter they saw at the same time as they consciously decided to press either the left or the right button. All this were done while their brains were monitored using fMRI-scanning. The scientists discovered patterns in the brains consistent with their choices up to 10 s before they reported that they were conscious of making the choice. It was also possible for the scientists to predict (with 70 % reliability) the choices about to be made up to 5 s before the test persons reported being conscious of a desire to act (Soon et al. 2008).

Both of these experiments have been criticized for their dependence on the memory and report from the test persons. An experiment designed to avoid this critique was done by Masao Matsushashi and Mark Hallett in 2008. They asked their participants to extend their finger as soon as they felt an intention to move. While they also found a readiness potential happening before the conscious intention to move, sometimes it was the other way around, and this suggests a more complex relation between readiness potential and intention than earlier suggested (Matsushashi and Hallett 2008).

The second kind of data concerns examples of confabulation, meaning that a person invents a reason to act differently from his or her actual cause of action. Experiments by Michael Gazzaniga and others on split brain patients have given many such examples. For instance, one patient was shown the word "walk" only to the right hemisphere, and he got out of bed and

started walking. He was then asked why, but the language center is in the left hemisphere, which had not seen the word "walk." He answered that he wanted to go and get a coke (Gazzaniga 2005). Experiments like these are relevant because they fit well with other experiments, suggesting that all persons confabulate, and this raises the question of how often we do.

Several experiments have been done where people were electrically stimulated in the motor area of the brain without knowing it, and the stimulation made them move their fingers. When asked why they moved their fingers, they answered that they had chosen to do so of their own free will. There are even some experiments where scientists stimulate an area of the brain and people say that they feel an intention to perform a certain act. When more electricity is put to the same area, they report that they have actually performed the act, even if they have not.

Gazzaniga argues that there is an interpreter in the brain which gives us the sense of a self in charge. And there are many examples of how brain damage can influence personality, areas of the brain can be triggered to cause various desires, and other examples which suggest that consciousness is totally dependent on what happens in the brain. This raises the question of whether or not the self is just an epiphenomenon with no causal influence. On the other hand, it seems that evolution must have selected consciousness for a reason, so that it actually must contribute somehow.

To sum up, there are many positions to choose between in the free will debate, and all of them have their problems. With all the new information coming from the neurosciences, there is every reason to believe that the debate will continue.

[Free will](#)

Description

By freedom we can refer to several different things. When we can talk about freedom in a political or social sense, we are referring to the autonomy of individuals or certain human groups to set their own legal and moral standards or form their own government. To be free in this

sense is to be independent from legal control (or oppression) that comes from outside the individual (or the group). This implies that there is an underlying, basic notion of freedom: To be free is to be able to realize one's desires without external constraint. In this sense, one is free when one takes the job one wants or chooses what kind of clothes one wears. Philosopher Robert Kane calls freedoms such as these surface freedoms. But there is also a deeper kind of freedom, a freedom to have an influence on one's own desires and beliefs.

To see the difference between surface freedoms and deep freedom, consider the following case. Imagine that there is a man, let us call him Thomas, who has always wanted to be a fighter pilot. Given the notion of surface freedom, we would say that Thomas is free, if he can become a fighter pilot and is not coerced to do something else. But the fact that Thomas has this surface freedom does not mean that he is free in a deeper sense. Let us further imagine that his father, a fighter pilot himself and a big Top Gun fan, had had Thomas genetically engineered to be extremely responsive to his wishes. Of course his father wants Thomas to become a fighter pilot and makes him watch Top Gun all the time. Thus, Thomas forms an unstoppable desire to be a fighter pilot. Now, it seems that Thomas is not free in the deeper sense that we just described. In what follows, we will be discussing the nature and the possibility of freedom in this deep sense.

The Problem of Free Will

Discussions and debates of this kind are often conducted under the heading of "free will." The issue, however, far exceeds individual choice. What we are interested here are issues such as the criteria for moral responsibility, determinism in nature, the nature of alternative future possibilities, causation, and rationality. Thus, there is no single "problem of free will." Instead, we have a cluster of problems and a cluster of answers (Kane 2002 has essays on all the relevant issues).

Having said that, we can present the following basic outline of the problem of free will. Normally, humans think that they are free to choose

what they want. The implicit assumption here is that there are alternative possible futures, say, a future in which Thomas is a fighter pilot and another where he is not. Further, it is Thomas' choice that makes the difference (among many other things, of course) between these alternative futures. The problem is that given what we know about the natural and physical world through science, it seems that human beings are part of that physical world and that the future events of the world are determined by the past and the laws of nature. Further, the choices we make should be based on good reasons: Should those reasons not determine our choices? In the case of Thomas, it seems that Thomas' reasons for his choice are not in his control. Instead, they are determined by his psychology and his environment.

A further question can then be proposed: How could Thomas be morally responsible for his actions, if they are caused by events that are out of his own control? Our basic intuition is that a necessary condition for moral responsibility is the power to do otherwise. Further, this power can only be realized by rational reflection of different alternative actions. If a person has no choice, then it seems that he or she is not morally responsible. This is the reason why we normally do not hold animals morally responsible. They lack the power of rational reflection and, thus, cannot choose between alternative actions. But can we really choose between alternative actions if our actions and choices are determined by past events (be they reasonable or not)?

Several solutions to these problems have been presented. We can sort out the positions by examining the kinds of freedom they allow:

1. According to classical compatibilism, we are free if we have the freedom of self-realization. In other words, we are free to the extent we have the power or the ability to do what we want and we are not subject to any external constraints.
2. Many "new compatibilists" hold that free will entails the freedom of rational self-control. What this means is that to be free is to understand and reflectively evaluate the reasons that one has for wanting to act in a certain way. Further, one needs to be able to control one's own behavior according to reflected reasons.
3. Some libertarians hold that free will requires the freedom of self-determination. What they mean by this is that one is free to the extent one has the power or ability to act on the grounds of the character, beliefs, and motivation that one have oneself influenced. The idea is that the person herself is the one who is ultimately responsible of her character and motivation.
4. Finally, many libertarians claim that the previous type of freedom includes a deeper kind of freedom, the freedom of self-formation. This freedom entails that one has the power to shape one's own will in a way that is undetermined by the past self-forming decisions or actions.

We can now look at these positions in more detail.

Compatibilism

There are many types of compatibilist analysis of free will. I will briefly examine two: classical compatibilism and what we might call "new compatibilism." Compatibilists agree that (a) all human actions are determined by antecedent causes (past events) and laws of nature, that is, they believe that determinism is true, (b) that free will and moral responsibility exists, and that (c) free will and determinism are compatible.

For the classical compatibilist, there are only surface freedoms, no deep freedom. The only freedom is the freedom of self-realization: We are free to the extent that we have the power to do what we want and are not constrained by external factors. Notice how this way of defining freedom says nothing about alternative futures. No alternative possible futures are required to be free. To be free is to act on the basis of one's own beliefs and desires and not be constrained.

It is easy to see how such a freedom is compatible with determinism. Consider the following example. Let us say that Thomas decides to cycle to work by bus one morning. Was this a free act? The classical compatibilist would analyze the situation as follows. Did Thomas want to go to work by bike? If he did and was not constrained

by anything external to him, then the act was free. It need not be possible that Thomas had had the power to do something else, say, take the bus instead of cycling. It is enough that if Thomas had decided to take the bus, it would have happened (given that there had not been any external constraints). But given Thomas' beliefs, desires, and his character (Thomas hates pollution and cars), it was impossible for him to choose any other means of travel than his bike. This way of understanding Thomas' freedom to choose is sometimes called hypothetical freedom: Thomas cycled to work because he wanted to and if he had different desires, he could have acted upon them, since there was no external constraint.

The major problem with classical compatibilism is that it does not accommodate compulsive or otherwise engineered desires and motivations. We see this, if we return to our earlier example of Thomas, the fighter pilot. In that case, Thomas is free to become a fighter pilot in the sense of self-realization, but Thomas has no control over his desires and motivations. The same thing can be said about pathological desires as well. Let us say that Thomas gets a metal fragment in his brain in a training accident that makes him to want ice cream all the time. He then goes and gets ice cream. This sort of compulsive behavior would be considered free on classical compatibilism.

Several contemporary compatibilists, such as Harry Frankfurt and Daniel Dennett, have argued for a deeper compatibilist freedom to avoid the problems of classical compatibilism. It is not enough to have the power to act on one's desires, one also need the power to reflect, evaluate, and control one's own reasons and the subsequent behavior (see, e.g., Dennett 2004). This involves a distinction between first-order and second-order desires. Let us return to Thomas, the fighter pilot. The contemporary compatibilist would say that Thomas has a strong first-order desire to become a fighter pilot and nothing prevents him from choosing to become one. But this does not mean that he is free. He is free in the sense of self-realization, but not in the sense of having rational self-control. For Thomas to be free in the sense of having rational self-control is for him to have the

power to evaluate his reasons for wanting what he wants and adjust his behavior according to such second-order desires. Given that Thomas is both genetically and socially programmed to become a fighter pilot, he does not have such control and, therefore, is not free.

Libertarianism

A libertarian is a person who believes that (a) indeterminism is true and determinism is false, (b) free will is not compatible with determinism, (c) and that we can make sense of indeterministic free will (O'Connor 1995 has essays for and against libertarianism). So the libertarian has to advance two kinds of arguments: arguments for the fact that compatibilist freedoms are not enough or are incoherent and forward a theory of indeterministic free will.

The most famous argument for the incompatibility of free will and determinism is the consequence argument (van Inwagen 1983). The argument can be summarized like this:

1. There is nothing we can do to change the past and the laws of nature.
2. Our present actions are the necessary consequence of the past and the laws of nature (determinism).
3. Therefore, there is nothing we can do to change the fact that our present actions occur.

To put it in another way, we are unable to do otherwise than we actually do. It follows from this that if determinism is indeed true, no one ever has the power to do otherwise.

The most common way to respond to this argument is to insist that the power to do otherwise is not a necessary condition of having free will. Compatibilist freedoms, such as the aforementioned freedom of self-realization and freedom of rational self-control, do not require the power to do otherwise. The libertarian response at this point is that even if the power to do otherwise is not necessary for free will, the notions of control and responsibility are. Compatibilists, they argue, cannot make sense of the deep seated intuition that to be free is to be the agent of one's own actions. For the libertarian, the person herself must be ultimately responsible for her character and motivations that are underdetermined

by past events. And this is what compatibilism cannot offer.

The second problem that libertarians have to deal with is that indeterminism does not seem to give any more support to free will than determinism. If there is genuine indeterminacy in nature, say, quantum indeterminacy of some kind, the outcomes are random, that is to say, nothing determines them. This does not help free will either: To have free will is to have the power to influence what possible future actualizes. If indeterminism is true, possible futures are realized randomly, not by human deliberation.

The first issue in a libertarian theory of free will is whether libertarian free actions have causes or not. The compatibilist argues that if actions do not have causes (reasons, desires, etc.), actions are merely random and completely irrational. Thus, to be rational, actions need to have causes of the right kind. The so-called non-causal libertarians (sometimes called simple indeterminists) claim that free actions do not have causes in any meaningful sense. Volitions are, according to this view, basic mental states that are not caused by anything.

Most libertarians, however, affirm that free actions do have causes. They reject non-causal libertarianism, because it is not able to explain how basic, non-caused volitional states are related to reasons for actions. Free will cannot simply appear from nothing without any reason. What the libertarian must do here is to show how free actions are caused, but not determined by factors that are out of the control of the agent. One possibility is to say that some extra factor – a nonnatural factor – comes in at the point of decision making that causes one alternative future to be realized. Usually, this is achieved by arguing that there exists a nonphysical and nonnatural soul that can have physical influence without being itself part to the causal nexus of past events.

Another possibility is to argue for what are usually called event-causal theories of free will. The event-causal theorist admits that there is a chain of causes leading up to the free act of the agent. The agent's reasons, motivations, and character are indeed causally efficacious. So far

this sounds like compatibilism. What the event-causal libertarian adds to this is that the agent must be responsible for the sufficient reason or motive for the action occurring. This immediately raises the problem of endless regress. If Thomas needs to be responsible for A, he needs to be responsible for his reasons to do A. To be responsible for these, he needs to do B and be responsible of his reasons for B and so on. Event-causal theorists attempt to sever the regress by introducing choices that determine the agent's will and character for subsequent events. These are called will-determining choices. Will-determining choices are choices that we make in conditions of uncertainty about what we want and where there is the possibility to do otherwise. Once such a choice is made, it causes the agent to make similar choices in the future.

Finally, many philosophers, such as Roderick Chisholm, have argued for agent-causation to give robust content to the freedoms of self-determination and self-formation. The event-causal theorist, as we have seen, argues that free actions are caused by antecedent will-determining choices, will-determining events. Contrary to this, the agent-causal libertarian argues that it is not enough that our actions are caused by antecedent events that we have control over, they have to be caused by the agent itself in some more robust sense. Thus, freedom must involve some kind of basic or brute fact agent-causation between the agent itself and the body of the agent. The nature of the agent itself can be understood in terms of the soul, in which case the agent-causal theory would be an extension of dualism, or in terms of some materialistic theory of what persons are, so far as the theory does presuppose that persons are identical to their bodies.

Agent-causal theories are open to criticisms as to the exact nature of the causation between the agent and her body. It seems that the agent-causal theorist must introduce a new factor into the causal mix, a factor that is not part of the ordinary flow of natural events. Be this new factor a materially constituted agent or essentially nonphysical agent (a soul), one still has to explain how this nonnatural thing can have physical

effects. The nature of causation involved, the critic claims, is mysterious.

Hard Determinism and Mysterianism

There are those who reject both libertarianism and compatibilism. The so-called hard determinist (contrary to compatibilists who are sometimes called soft determinists) will claim that (a) determinism is true and indeterminism is false, (b) free will is incompatible with determinism, and, therefore, (c) there is no such thing as free will. Free will in any meaningful sense of moral responsibility, they claim, is not compatible with determinism and determinism is what science requires us to believe. Thus, science trumps our everyday idea of free decisions and responsibility. We need to learn to live without the idea of free will.

Another, more popular, position is one that we could call mysterianism. The classical mysterians, such as Immanuel Kant, and contemporary mysterians, such as Peter van Inwagen, argue that (a) either indeterminism or determinism is true, (b) free will is incompatible with both determinism and indeterminism but (c) we cannot help but to believe in free will anyway (van Inwagen 1983). Free will, according to van Inwagen, is the power to do otherwise on the basis of rational deliberation. As the consequence argument concludes, if determinism is true, then we have no power to do otherwise. But, for the reasons already mentioned before, we lack that power to otherwise even if indeterminism is true. At this point, the compatibilist would say that we should give up the idea of free will as being able to otherwise. Van Inwagen argues that we really cannot do this. The problem is that free will as a power to do otherwise is constitutional to our everyday understanding of ourselves and our actions in the world. We cannot live without it. So, we find ourselves in a situation where we have no idea how free will is possible, but must believe in it nevertheless. Free will is, therefore, a complete mystery.

Science, Determinism, and Free Will

As we can see, ideas about the laws of nature are crucial for the whole free will debate.

Determinism is usually defined in terms of laws of nature: Determinism is true if at time t , everything that has happened in the past in conjunction with the laws of nature make only one future possible. But this way of defining determinism has some serious problems.

It is not the case that universal determinism is supported by contemporary physics. Quantum indeterminacy, complexity, and chaotic systems suggest that there is some indeterminacy in physical systems. This, one thinks, is good news for the libertarian: Science does not support determinism. Things are not that simple. Most philosophers and scientists still believe in determinism in human behavior, because of developments outside physics. The progress of biology, social sciences, neurosciences, and psychology has produced massive amount of information about the genetic, cognitive, social, and neurological causes of human behavior. There might be indeterminacy at the fundamental physical level, but the more we find out about human behavior, the more we see how it is driven by causes that are outside human control. The main issue, it seems, is not really whether determinism or indeterminism is supported by contemporary physics, but rather the suggestion of contemporary neurosciences, biology, and social sciences that there are many different kinds of non-voluntary causes that influence our decisions.

Consider the following argument for neurobiological determinism. If we reject the existence of nonnatural factors influencing human organisms (souls, etc.), then we must conclude that human brains are physical systems. As all other physical systems, everything that goes on in the brain has sufficient physical causes – causes that are explicable in terms of neuroscience. Since every mental event is also a physical event with sufficient physical causes, the mental events themselves make no difference to what happens next. Our thoughts and acts are, thus, necessitated by the physical functions of our brains, not our choices, reflections, or deliberations.

One way of responding to the problem of neurobiological determinism is to argue that psychological theories do not provide laws in the sense of universal generalizations. Instead, they

produce idealized models of certain, very specific causal relationships. Instead of one single “complete picture” of what happens in the mind, psychological sciences give us laws that track the truth in one very particular area of human cognition and brain. But because of the piecemeal nature of these laws, they do not, all by themselves, rule out the possibility of other factors influencing the brain in some way. Another possibility is to argue that the complexity of our brains as physical systems, higher-level events, or systems can have influence on lower-level events or systems. This is usually called top-down influence. Top-down influence, the argument goes, makes complex interaction between thinking, action, and deliberation possible to such an extent that the human action and decision making is not subject to any clear-cut laws. Both these solutions claim that given the sciences we now have, we do not know whether all mental events have sufficient physical causes that can be given in terms of low-level neuroscience. Thus, when we understand what science actually tells us, we see that neurobiological determinism is a philosophical position rather than something simply flowing out of the sciences of the mind themselves (Horst 2011).

God, Freedom, and Future

It seems that if the traditional theistic God were to exist, certain analysis of what free will is would be ruled out. Traditionally, one of the biggest problems has been the seeming incompatibility of God’s foreknowledge and human freedom. One way to look at the problem is this: If God knows the future and is omnipotent, then free creatures cannot choose otherwise than what God has intended. Further, if God exerts providential control over the world and knows what is going to happen because of this, it seems that the future will be set regardless of how we decide to act. This is a view known as theological fatalism.

There are several different ways to steer clear of theological fatalism. We can get the best grip on these solutions, if we present them as responses to the following simplified argument for theological fatalism. The argument here is based on one single human action. Notice,

however, that if the argument works, it can be applied to all human actions.

1. God knows at t_1 that Thomas will read *Crime and Punishment* by Dostoyevsky at t_2 .
2. God’s beliefs are infallible, that is, God’s beliefs cannot be false.
3. Thomas is free to read *Crime and Punishment* at t_2 , if he can choose not to read *Crime and Punishment* at t_2 .
4. Given 1. and 2. Thomas cannot choose not to read *Crime and Punishment* at t_2 .
5. Therefore, Thomas is not free: He is determined to read *Crime and Punishment* at t_2 .

This argument is rather similar to the consequence argument discussed earlier. Premise 1 is based on the classical notion of omniscience, according to which, God’s knowledge is perfect. In other words, God knows everything that can be known. Premise 2 is based on another standard component of classical theism, that is, God possesses his properties, omniscience in this case, necessarily. If God is necessarily such that He knows everything that can be known, then it follows that God’s beliefs cannot be false. God is, therefore, infallible in all possible worlds. Premise 3 invokes the idea that alternative possibilities are necessary for free will. That is, if it is not possible for Thomas to realize the states of affairs of reading *Crime and Punishment* at t_2 , then Thomas is not free. But if 1 and 2 are correct, then Thomas cannot choose not to read *Crime and Punishment* at t_2 , because that would mean that one of God’s beliefs is wrong.

There have been several attempts to solve this problem in the history of theistic philosophy and theology (see Zagzebski 1991). First, according to hard theological determinism, the argument is sound and humans are not free. Second, soft theological determinism accepts 1 and 2, but denies 3. Instead, it claims that God indeed knows that Thomas will read *Crime and Punishment* at t_2 and Thomas cannot do otherwise, but this does not impinge upon Thomas’ freedom. Both soft and hard theological determinism have been relatively popular in Christian philosophy and theology. According to thinkers such as Augustine and Jean Calvin, nothing in the created world happens by chance. Instead, everything

that happens is both ultimately determined and known by God. If the theological determinist does not want to reject free will altogether (as the hard theological determinist must do), a compatibilist analysis of human freedom seems to be the only option.

Contrary to this, some have claimed that it might be possible to hold onto libertarian free will and theological determinism at the same time. This solution invokes the atemporality of God, namely, the idea that God does not have temporal properties. Let us call this the Boethian solution (after Boethius). An advocate of this view would deny 1 and claim that since God is atemporal, God does not know anything at t_1 . Instead, God has all his beliefs “timelessly,” that is to say, God’s having the belief that Thomas reads *Crime and Punishment* at t_2 is not related to our time in any way. Further, this allows Boethius and other eternalists (such as Aquinas) to say that since God does not have his infallible belief at any time before (or after), Thomas actually reads *Crime and Punishment*, Thomas is free to make the choice and whatever that choice may be, God knows it eternally.

Fourth, the so-called Molinist solution (after Luis de Molina, sixteenth century Jesuit) denies 3 and argues that God’s knowledge does not remove Thomas’ freedom to choose, because God knows what Thomas would freely choose in all possible circumstances. In other words, God knows that Thomas will read *Crime and Punishment* at t_2 , but he knows this by not determining the event, but by knowing what Thomas will freely choose in circumstances that He puts him. Thus, Molinism is committed to the existence of a special type of knowledge, that is usually called middle knowledge. Medieval thinkers distinguished God’s free knowledge from his natural knowledge. God’s natural knowledge has to do with abstract truths (mathematical and logical truths) that are necessary and independent of God’s will. God’s free knowledge is His knowledge of contingent truths that are dependent on His will (truths about the created world). To these two types of knowledge, Molina added a third way of knowing: middle knowledge. Middle knowledge is knowledge about

truths that are, similarly as His free knowledge, contingent, but not dependent of His will. In our case, God would have access to middle knowledge that would be something like this:

If Thomas is put in circumstances C, he will freely choose to read *Crime and Punishment*.

As we can see, middle knowledge is presented here in a counterfactual form. In the literature on Molinism, such propositions are often referred to as counterfactuals of freedom (or counterfactuals of creaturely freedom). By knowing the truth of such propositions, God could know that Thomas will read *Crime and Punishment* at t_2 without removing Thomas’ free choice.

Fifth, many contemporary philosophers and theologians, such as Richard Swinburne, Keith Ward, and John Polkinghorne, defend a group of views usually called Open Theism. Open Theism accepts 2 but denies 1: According to Open Theism, God does not know at t_1 that Thomas will read *Crime and Punishment* at t_2 . But does this result in denying God’s omniscience? No, says the open theist, because omniscience requires only that God knows everything that can be known. Propositions of future free choices do not have a truth value before those choices are actually made and thus there are no truths to be known about them. In this way, God’s omniscience as well as libertarian free will is preserved. If one accepts Open Theism, one must also accept that God is, at least to some extent, temporal and does not determine the future completely.

All these solutions have their distinctive problems. The problems of theological determinism have to do with the problem of evil. If humans do not have libertarian free will, then it might seem that they are not responsible for moral evil, but God is. In other words, theological determinism sets the bar of a successful theodicy very high. The Boethian solution is believable if one has independent reasons to believe that God is atemporal and one can make sense of God’s atemporal believing. The biggest obstacle of Molinism is the so-called grounding problem. If Molinism is true, then there will be truths of what all possible free entities would do in all possible situations even

if God does not create a world at all. What makes middle knowledge true? It is not God's nature, nor is it his choices, but there is nothing else left. Further, the critic of Molinism can ask how God knows these truths. They do not resemble abstract and necessary truths of logic and mathematics that God could know by knowing his own nature and mind. Neither are they truths that God knows on the basis of what he has created. Finally, Open Theism has its own problems as well. One problem is that many do not recognize the existence of propositions about future actions whose truth value is indeterminate. Another problem is that on Open Theism, it looks as if God's promises could fail to be realized. Since God does not know the future (as there are no truths to be known about future free choices), it is possible that some free choice will thwart God's plan. For many theists, preserving libertarian free will by giving up God's absolute providence is a price too high to pay.

[fMRI](#)

Description

Functional magnetic resonance imaging (fMRI) is the term used in general to describe a group of MRI techniques that are capable of tracking physiological changes in living tissue, as well as delineating anatomy. The term was first applied by Moonen and colleagues (1990) to denote MRI methods for the detection of the motion of water in processes such as vascular flow, capillary flow, diffusion, and exchange, and also for measuring the concentrations of various metabolites involved in the regional regulation of metabolism.

When Ogawa et al. (1990), Williams et al. (1992), Turner et al. (1991), and Kwong et al. (1992)

developed noninvasive methods in 1990–1992 that enabled MRI to localize brain areas associated with specific functional activity, the term “fMRI” rapidly became specialized almost exclusively to denote MRI techniques for the study of brain function. Entirely noninvasive, using only a set of carefully controlled magnetic fields, fMRI methods map local variations over time in either cerebral blood oxygenation or cerebral blood flow. The observed signal arises from the nuclear magnetic resonance of the proton nuclei of hydrogen atoms in the water molecules which make up most of the volume of brain tissue.

Because the international availability of MRI scanners capable of performing these specialized MRI techniques has rapidly increased, the use of fMRI has expanded dramatically in the fields of cognitive science, neurology, psychology, neuroradiology, and psychiatry. Never before has there been a noninvasive technique for studying the human brain which combines a spatial resolution of better than 1 mm with a temporal resolution of about a second (mainly limited by the slow response of blood flow to changes in neural activity). Typical research themes extend from the exploration of visual-processing brain areas mapped according to where light falls on the retina, to the spatial organization of brain areas responding to rewarding experiences. Recent studies measure how learning and memory processes remodel brain tissue, both in functional activity and even physical dimensions. It is now possible, by studying the functional brain activity of a given human volunteer subject in a task involving choice, to predict the outcome of the choice sooner than the subject is aware of their decision (Soon et al. 2008).

Self-identification

Science

The experimental techniques of fMRI are entirely derived from the physics of nuclear magnetic resonance. This is a very well-established area of science, which arose from the greatly increased understanding of the quantum physics

of atomic nuclei in the 1940s and 1950s. Fundamentally, the observable phenomena arise from the fact that some nuclei, such as protons, have a net spin, which means that their energy states are dependent on an applied magnetic field. This fact can be readily demonstrated using suitable easily constructed apparatus. The physics of condensed matter and basic thermodynamics are also involved in the quantification of the NMR signal, and hence in the creation of the cross-sectional grey scale images of brain tissue that form the raw materials of fMRI science.

The biophysical relationship between the MR image intensity changes and underlying changes in brain activity is not so straightforward. Considerable work has been devoted in recent years to understand the mechanisms of neural control of blood flow, and the process of oxygen extraction from the blood by metabolizing brain tissue. Some effort was also required to model accurately the important effect of deoxygenated blood, which is more paramagnetic than oxygenated blood, on the MRI signal. This effect is utilized in the most popular form of fMRI, blood oxygen level-dependent contrast (BOLD). Empirical work, however, notably by Logothetis et al. (2001), comparing recordings from electrodes implanted in living animal brains with the changes in fMRI signal occurring nearly simultaneously in the same location, has given researchers great confidence that what they observe is not artifactual.

The design of fMRI experiments and the analysis of fMRI data, on the other hand, are far more dependent on culturally dependent assumptions. For instance, early work in imaging neuroscience assumed that there are no interactions among the cognitive components of a task, so that to identify brain areas important to a particular task one would need only to provide two experimental conditions, with and without the task, and perform a simple subtraction of the functional images thus obtained. In time it was realized (e.g., Friston et al. 1996) that a mammalian brain is never idle, so that much better defined experimental conditions, and more sophisticated (e.g., factorial) analyses are required unambiguously to isolate brain areas with specific

functions. Methods for analysis of brain imaging data are still undergoing rapid development.

Beyond this, what still underlies much of imaging neuroscience consists of an uneasy and usually unreflective combination of naive empiricism, positivism, behaviorism, materialist reductionism, and philosophical idealism. The choices of explanatory concepts and models are inherited largely from experimental psychology, and other relevant human sciences – anthropology, sociology, developmental psychology – are often ignored. The term “neuropsychology” has unfortunately come to denote (in the hands of Churchland and others) the use of the findings of fMRI and other neuroscientific results to justify a sometimes intolerant and fundamentalist atheism, but it can be strongly argued that such an activity, in the true meaning of the term “philosophy,” is greatly needed to clarify and refine the conceptual bases for imaging neuroscience.

Be this as it may, fMRI is now very well accepted as a methodology within cognitive science, neurology, experimental psychology, and psychiatry. Presentations relating to fMRI form about 20% of the proceedings of the annual meetings of the International Society for Magnetic Resonance in Medicine, and perhaps 70% of the annual International Conferences on Human Brain Mapping. Results based on fMRI are presented uncontroversially at meetings of the Society for Neuroscience and the Society for Cognitive Neuroscience, and at all major neurology and psychiatry conferences. Two journals, *NeuroImage* and *Human Brain Mapping*, have a high proportion of fMRI-based publications, and the high-impact journals *Science*, *Nature*, *Nature Neuroscience*, *Journal of Neuroscience*, *Neuron*, and *Cerebral Cortex* often publish fMRI-derived results.

Characteristics

fMRI is distinctive within the field of neuroscience in two respects. Firstly, most of the experiments involve human subjects. Much basic work has been performed with experimental animals, but this primarily addresses validation of

techniques to be applied with humans. The reason for this focus on human subjects is the excellent noninvasiveness of fMRI, which allows human subjects to be scanned indefinitely frequently. In the study of cognition and psychology, use of human subjects is highly desirable because humans are uniquely compliant in performing experimental tasks, and because most of the important theoretical questions in these fields relate primarily to our species.

The second respect in which fMRI is distinctive within neuroscience is its dependence on the “big science” of MRI physics. Scanners are expensive, and the researchers that invent and optimize fMRI techniques are highly skilled and highly paid scientists, invariably with PhDs in physics or related subjects. Major multinational high-technology companies, such as Siemens and Philips in Europe, and GE in the USA, produce thousands of MRI scanners per year in a highly profitable business, mostly supplying radiology departments of hospitals with instruments for clinical diagnosis and monitoring. Use of fMRI is an offshoot of this business, which allows brain scientists an otherwise inaccessible opportunity to use reliable, very powerful, and highly developed scanners to address fundamental questions of brain organization.

This second aspect makes fMRI also distinctive within neuropsychology and cognitive psychology, where typically the experimental equipment required is relatively simple and inexpensive.

Relevance to Science and Religion

Because the brains of populations of normal human subjects can be studied easily using the techniques of fMRI, a number of brain scientists have been attracted to the possibility of finding objective material correlates for mental states that have traditionally been associated with religion. It is commonly assumed that, to any mental state, or mental act, there corresponds respectively a brain state, or change in brain activity. Thus, several types of meditation have been studied (well reviewed in Pagnoni et al. 2008), where skilled and unskilled meditator subjects lay in the scanner while meditating, with a variety of

control conditions. One carefully performed recent experiment (Wiech et al. 2008) investigated the effect on pain thresholds and regional brain activation when symbolic religious images were shown to religious and nonreligious subjects, lying in the MRI scanner while a painful stimulus was applied. Another study (Schjødt et al. 2008) showed activation specific to the caudate nucleus, part of the dopaminergic reward system, when volunteer subjects were silently praying while being scanned.

Generally speaking, when subject groups have been carefully characterized in religion-related studies, significant fMRI-observable differences relating tasks to various brain areas were indeed found. The causal interpretation of such differences, associating them with religious training or socialization, of course remains difficult, but insight can perhaps be gained by referring to other simpler tasks that these brain areas are known to perform.

There remains the deeper problem of how to define the term “religion.” If this term is taken generally to denote coherent systems of belief and accompanying ritual actions, as is common in anthropological studies of non-Western societies, it perforce includes much of what one would more normally call “science” in the context of Western culture.

While this interdisciplinary discourse between the neurosciences and the humanities is still in its infancy, the anthropologist Victor Turner wrote presciently (1985) that “ritual can perhaps be thought of, however crudely, as given its momentum by brain neurophysiology.” A deeper understanding is currently being built of the brain systems dealing with reward and the emotions, through the work of Critchley et al. (2004), Schultz et al. (1997), and others, which often entails the use of fMRI, and it is to be hoped that these insights will permeate fresh thinking about the prevalence and necessity of human ritual action.

Sources of Authority

As regards the experimental techniques of fMRI, the primary sources of authority are the published

experimental results (Ogawa et al. 1990; Turner et al. 1991; Williams et al. 1992; Kwong et al. 1992; Ogawa et al. 1992) showing that changes in cerebral blood flow and oxygenation can be observed using the NMR methods. These experimental results have been replicated very frequently in labs worldwide. Correlations between such changes and the neural activity they are considered to indicate have been studied invasively in monkey brain (Logothetis et al. 2001) and often in rat brain (e.g., Yang et al. 1996). As available magnetic field strengths increase, and MRI methods improve, the colocalization of fMRI signals and neural electrical activity becomes more precise. Combining observed changes in blood flow and blood oxygenation with an appropriate calibration technique (Zappe et al. 2008) has enabled the mapping of oxygen extraction, a reliable index of neural work.

The data analysis methods that are now mostly used are those of classical parametric analysis, which is standard across the quantitative sciences, together with a growing use of Bayesian statistics. Various reasonably well-validated methods are used for data mining, and for inferring effective connectivity between brain areas. All of these methods are made authoritative by testing their mathematical correctness and consistency.

Interpretation of fMRI results rests on the known neuroanatomy, neurophysiology, and neurology of the brain. Authoritative knowledge in these areas derives from the same sources as the science of Neurology (q.v.)

Ethical Principles

The ethical principles guiding fMRI work on human subjects are those common to the medical profession – subjects are only examined after they have given fully informed consent. Since the technique has an exceptionally good safety record, with no dangers apart from the obvious ones such as ballistic ferromagnetic objects, human subjects very happily volunteer to be scanned for periods sometimes up to 90 min.

Most experimental paradigms involve presentation of stimuli or performance of a task while the subject is in the scanner bore, and generally these are fully described beforehand. For a few experimental paradigms, where it is an important component of the neuropsychological enquiry for the subject not to anticipate a particular task or stimulus, mild deceptions can be used.

Use of animals for validation or development of fMRI techniques is governed by widely shared legislative regulations that prohibit wanton infliction of pain.

Key Values

The first, most specific key value of fMRI is making the best use of the historically unprecedented opportunity of making explicit, in the form of images, the activities that take place within a person's skull. On the distance scale of a few millimeters that is accessible to MRI, it has become clear that our understanding of the relationship between the mind and the brain can be greatly enhanced. This has profound implications for the medical fields of psychiatry and neurology. It is likely to have a considerable impact on educational theory, microeconomic theory, anthropological theory, and linguistics.

Otherwise fMRI shares its values with many other sciences – integrity, scholarship, truthfulness, and explicitness.

Conceptualization

Nature/World

fMRI uses the physicist's conception of nature, comprising the range of entities that are amenable to precise quantitative measurement. This includes material objects down to the scale of the electron, the different forms of energy, and all well-established physical forces, such as electromagnetic and nuclear forces.

For fMRI scientists, the world is the physically known universe. Of course, there is a significant focus on living matter.

Human Being

The human being is considered as a biological being equipped with a highly developed complex brain, which enables unique functions including speech, abstract thinking, creativity, and the development of ethical categories such as morality, science, and art. Thus, humans are considered to be distinctive from the rest of the animal world in virtue of the unique capacities of the human brain.

Life and Death

Life is conceptualized as the presence of physical functions in biological systems ranging from bacteria over plants and animals to humans. In the human body, it includes functioning of the different organs, including the nervous system. Death is considered the cessation of such physical functions. A special case, which has raised ethical challenges for Medicine, is that of so-called brain death, which is observed in intensive care medicine. Here, non-brain bodily functions are maintained, but there is no evident brain activity.

Reality

Reality is considered the physical world around us that humans can observe with their senses.

Knowledge

Knowledge is understood to have an objective dimension, such that it is the wisdom that can be transferred in a verbal form from one person to the next, or has been written down in books or libraries. However, knowledge is also understood to have a subjective dimension, which is taken to be the amount of information a person can retrieve from memory voluntarily, or by being cued.

Truth

Truth is conceptualized as the supreme reality underlying facts and rules. Accordingly, truth is assumed to be absolute or universal, which humans can grasp only partially.

Perception

Perception is the conscious sensation of the forces and influences the external physical

world exerts on living beings. Diseases of the human brain may disrupt or impair perception.

Time

Time is the fundamental category of ongoing change in the world. Humans can measure time objectively and perceive it owing to the changes observed in the surrounding environment. Human perception of time can be affected by the focus of attention or impaired by diseases of the brain.

Consciousness

Consciousness is the responsiveness of subjects to any physical stimulus in the outside world. It can be graded in different levels of alertness ranging from drowsiness to full alertness, which comprises crystal clear orientation concerning location, time, situation, personal biography, and full mental capability. Diseases can impair consciousness globally, or in differentiated fashions.

Rationality/Reason

Rationality is a foundation of accountable and responsible human behavior and of understanding reason as ultimate authority. It is impaired in mental diseases such as dementia or neuropsychological disorders.

Mystery

Often mystery is considered to be contradictory to modern medicine, including the brain sciences.

However, better-informed scientists recognize that the operations of such an extremely complex system as a human brain may be very elusive to characterize or explain. Even the conceptualization and terminology of cognitive science remain problematic. Thus, fMRI, like neurology, acknowledges, in principle, a place for mystery, that is, that which is as yet unknown. In this view, mystery is understood as potentially explicable once the research questions have been properly framed, appropriate experiments conducted, and the resulting scientific knowledge accumulated and understood.

Relevant Themes

A critical issue in fMRI, as indeed with the other subdisciplines comprising brain science, in the context of “Science and Religion,” is the notion of subjectivity. Subjectivity includes the individual’s perception of the outside world and their own body, as well as their individual reasoning and evaluation of personal experiences, short-lived thoughts, and long-standing ethical categories. An increasing number of fMRI studies have successfully used the subjective reports of experience as a useful parameter, localizing brain areas specific to such conscious percepts.

Description

The label “functionalism” comprises a variety of schools of thought pertaining to different disciplines, and certain precautions should therefore be taken if it is to be used properly. For some authors, functionalism is an explanatory schema,

applicable to nearly all complex systems, according to which each and every part of a system fulfills a necessary, though not always explicit, function for the system as a whole. In this sense, functionalism has significant teleological, finalistic, or at least etiological connotations (Huisinger 2003). Other authors define functionalism as the ontological thesis that function is all-important and stuff (or composition) irrelevant. In this sense, functionalism is a basic ontology which intends to offer a (modern) philosophical alternative to the classical type of metaphysics, that is, to substance metaphysics. The triad system-structure-function substitutes for the old noble concept of substance. Functionalism and structuralism are therefore akin to philosophical positions, even though sometimes they are seen as opposed to each other as a dynamic to a static approach (Ferrater Mora 1994, p. 412). In any case, the precise relationship between these two views of functionalism, the teleological (or better, quasi-teleological) and the ontological, can only be determined through a careful analysis of the use of the concept of function as well as functionalist accounts and explanations (for an attempt in this direction, see Bunge and Mahner 2001).

Functionalism is important in at least five intellectual domains: social science, biology, architecture/technology, psychology, and philosophy of mind. After saying some words about each one of the first four areas, we will focus our attention on the fifth, where functionalism is one of the major doctrines. This expository sequence has an additional benefit: In areas 1–3 the quasi-teleological view of functionalism (let's call it adaptationist functionalism) prevails, whereas in area 5, the ontological view of functionalism (say formalist or black-box functionalism) predominates, psychology (area 4) being a transitional ground from one sort of functionalism into the other.

Let us begin with social science. Here functionalist views (represented, among others, by sociologists Emile Durkheim, Talcott Parsons and Robert Merton as well as by anthropologists Bronislaw Malinowski and A.R. Radcliffe-

Brown) underscore the context in order to explain the nature and function of a given social institution: The adaptability of this to the circumstances amounts to its functionality. A second emphasis is on the organic unity of society, which highlights the homeostatic nature of social systems, that is, their tendency to maintain equilibrium and return to it when external shocks disturb the balance among social institutions. Functionalist theories have been criticized for their equilibrium bias and social conservative orientation. But modern neo-functionalism, which takes cybernetic concepts into account, and autopoietic systems theories, like those of Niklas Luhmann, show that functional analysis need not be static.

Functional analysis has also been applied to religion. Different authors highlight different functions of religious institutions for society, ranging from its power of integration (e.g., Durkheim) to its ability to cope with experiences of contingency and reduce complexity (e.g., Luhmann). They contribute to the survival of the social system as a whole. American sociologist Robert Bellah fruitfully combines a structural-functional approach to religion with the historic-genetic study of human social evolution. In science and religion dialogue, functional approaches are advocated above all by Ralph W. Burhoe, whose scientific theology intends to be a functional equivalent of religion in the development and survival of human culture. Theologian Philip Hefner suggests that Burhoe's view must be complemented by a functional understanding of science within a religious or theological framework (Meisinger 2003).

In biology, functionalism usually also takes the form of adaptationism. This is the thesis that all (or at least most) phenotypic traits in biological populations are ultimately adaptive, that is to say, a solution to a hypothetical design problem assuring the satisfaction of individual or group needs. The main difference between functional explanations in sociology and biology (apart from the sense of intention, purpose, or goal characteristic of human life) is that the latter can furnish a concrete mechanism which selects adaptive traits, that is, natural selection, whereas

no specific mechanism of cultural selection is known. As a matter of fact, biological adaptationism is a program which, in contradistinction to biological pluralism, views natural selection as the only important cause of the evolution of a trait. In some cases, like in Daniel Dennett's thesis of evolution as a substrate-neutral algorithmic process, evolution is reduced to natural selection to such an extent that critics speak of panselectionism (Bunge and Mahner 2001, p. 87). Other outspoken advocates of biological adaptationism are Ronald Fischer, John Maynard Smith, William Donald Hamilton, and Richard Dawkins. Critics of adaptationism (most notably Stephen Jay Gould and Richard Lewontin, who in 1979 published together a very influential paper on the matter, but also Sewall Wright already in the 1930s) contend that the power of natural selection to shape individual traits to an evolutionary optimum is thus overemphasized and the role of developmental constraints and other genetic factors ignored. Selection is a sorting process, not a source of qualitative novelty.

Regardless of specific differences among them, all sorts of technology tend to be adaptationist-functionalist because technologists' tasks consist of designing artifacts that perform well-defined, preassigned functions. The concrete mechanisms which realize those functions are moreover of the outmost importance. Users of artifacts, however, need not care about such mechanisms and may adopt a more formalist, still functionalist stance. Adaptationist functionalism in technology can be radical or moderate, depending on whether everything is subordinated to a key function or other considerations are also taken into account. A good example of radical adaptationist functionalism is found in architecture, where starting in the 1920s Louis Sullivan and Frank Lloyd Wright advocated the principle: "Form follows function," which captures the belief that all characteristics of a building must be driven solely by its function. This program was taken even further by the Bauhaus, which celebrated an austere functionalism with little or no ornamentation. Postmodern architecture was a reaction against such a latent utilitarianism.

Successful technology is only moderately functionalist. Then, efficiency is not all-important, and other values, such as social profit, play a balancing role (Bunge and Mahner 2001, p. 92).

In psychology, the functionalist school of Chicago, inspired by William James and founded by James Rowland Angell at the turn of the nineteenth into the twentieth century as reaction to the psychological structuralism of Wilhelm Wundt, adopted an adaptationist approach to mental activities. Mental life and behavior were conceived as an active adaptation to the person's environment in order to satisfy the needs of the organism. Pragmatists John Dewey and Georg Herbert Mead shared this view. (Radical) behaviorism is also often characterized as functionalist. But in spite of J.B. Watson having been a close disciple of Angell, the behaviorist concept of function has different connotations than that of the Chicago functionalists: These retained an emphasis on conscious experience, underlined continuous interaction of environment and organism, and accepted the existence of mechanisms of action and reaction not determined by conditioning; moreover, controlled experiments played almost no role in their theories (Ferrater Mora 1994, pp. 410–411).

The most important contemporary descendant of this form of psychological functionalism is evolutionary psychology, a discipline based on the idea that studying the evolutionary functions of consciousness is necessary for the complete understanding of the human psyche. Its best known advocates are Leda Cosmides and John Tooby. According to them, the main theses of evolutionary psychology are: (1) rather than with organs, psychology deals with functions or purposes, with every function susceptible of being instantiated in a variety of systems; (2) psychological functions are subject to natural selection; (3) there are innate psychological mechanisms, all of which are information-processing programs that map informational input into behavioral output; (4) the psychological mechanisms in charge of learning special tasks are Darwinian algorithms which organize experience into adaptively meaningful schemas or frames. This

combination of adaptationist and formalist functionalism, akin to Dennett's, has been seriously challenged. Not all types of functions are substrate independent. Furthermore, it is not clear what "psychological mechanism" is supposed to mean, since a mechanism is a process within a concrete thing: There are brain mechanisms, but not psychological ones. There is, finally, no evidence for the algorithmic nature of all cognitive processes, which turns evolutionary psychology into a merely speculative theory (Bunge and Mahner 2001, p. 88). The proposals of evolutionary psychology and the criticism they have provoked lead us directly into our next item.

Functionalism in the philosophy of mind is the doctrine that asserts what makes something a mental state of a particular type is not its internal constitution, but rather the way it functions, or in other words: not what it is made of, but what it does. Mental states are thus functional entities, whose functions are usually taken to be those of mediating between certain stimuli (inputs) and given mental states on the one hand, and certain behaviors (outputs) and resulting mental states on the other. It was Hilary Putnam's and Jerry A. Fodor's converging contribution to model these functions using computing machines and programs, initially Turing's machine, as inspiration (see, for example, Putnam 1975). Mental states are just like the states of an automaton and can be characterized in terms that involve only logico-mathematical language (for relations between states) and terms for input signals and behavioral outputs, that is, in entirely nonmental terminology. Both machine and non-machine versions of functionalism insist on such nonmental characterizations of mental states. Non-machine versions turn to psychological theories instead of computers as a guide in their depiction of functional identities. A priori or analytic functionalists (e.g., David Lewis, Sydney Shoemaker) appeal to common-sense psychological theory, whereas empirical functionalists (e.g., later proposals of both Putnam and Fodor, also Gilbert Harman) appeal rather to one or other scientific psychological theories. Moreover, the former regard functional analyses as elucidations of the

meanings of mental terms, the latter see them instead as substantive scientific hypotheses (for these categorizations of functionalists, see Block 1978, pp. 266–271; for an outstanding overview of functionalism see van Gulick 2011).

In order to understand functionalism's core idea more deeply, it may be helpful to remember that in the 1960s, functionalism was initially proposed as a solution to the mind-body problem, which at that time seemed stuck in a dead end. Cartesian dualism postulates a special mental substance; behaviorism identifies mental states with behavioral dispositions; and identity physicalism reduces mental states to brain states. Fundamentally avoiding dualism, functionalists intended to follow a middle road between behaviorism and physicalism, which were the two materialist alternatives to dualism. On the one hand, (logical) behaviorism argues that mental terms are synonymous with dispositional terms (which mediate between stimuli and behaviors, inputs and outputs), offering thus a relational account of mental properties, but at the cost of ultimately depriving them of all causal import. On the other hand, identity physicalism sustains that mental terms refer to neurophysiological states, so that mental processes must have the causal properties of the corresponding neurophysiological processes. For the identity theorist, the concept of mental causation is therefore as rich as the concept of physical causation. But for him mental concepts are not interdefined; the relations among them are not constitutive. Functionalism can make sense of both the causal and the relational character of the mental. And the way to do it is to tie both aspects together or, in other words, to construe the concept of causal role so that a mental state can be defined by its causal relations to other mental states (for this depiction of functionalism as capturing the best features of the materialist alternatives to dualism, see Fodor 1981, pp. 119–121; see also Lycan 2003).

This move gives mental states a degree of objective reality which cannot be accounted for by behaviorism. But at the same time, it questions the one-to-one correlation between mental and

brain states which forms the backbone of identity physicalism. Mental states are not uniquely realized (in human brain states), as identity physicalism requires; rather, they can be multiply realized, not only in (terrestrial) biological systems, but also in other kinds of systems (say, computers or Martian brains), provided they still play the same causal role, i.e., function. This thesis, known as multiply realizability, comes originally from the computer-science distinction between hardware and software: The mind is like software which can be run on different types of hardware. Many of the strengths of functionalism in the philosophy of mind (and its very character of formalist or black-box functionalism), but also many of its weaknesses, are connected with such a claim. Multiple realizability as such has been strongly criticized (for example, Bunge and Mahner 2001), but most troubling are some of its consequences, graphically pointed out by critics of functionalism. Before going on to deal with that point, we would like to observe that, all in all, functionalism has succeeded in advancing a very compelling version of non-reductive materialism, which has fostered the development of fields like cognitive psychology and artificial intelligence.

The main objection against functionalism is, of course, that it does not adequately characterize mental states. According to their content, the traditional view in the philosophy of mind divides mental states into intentional and qualitative. Some critics of functionalism contend that intentional mental states (beliefs and desires) cannot be completely characterized in functional terms since that leaves out the distinctive “intentionality” or the “aboutness” of the mind. This is also the intent of John Searle’s famous “Chinese room” argument. Someone who does not understand Chinese is placed, well equipped with books and writing materials, in a room with two hatches. Through one hatch Chinese symbols are handed to this person, who, following the instructions laid down in the books, arranges on a paper a different combination of Chinese symbols and sends it out through the other hatch. It turns out that she has correctly answered questions in

Chinese. Would the person in the room really be said to understand Chinese? The point is that the system including the person, the books, and the written materials is functionally, but not psychologically, identical to a person who really understands Chinese. Since functionalism holds that two functionally equivalent systems should also be the same in regard to their mental states, this is incompatible with functionalism. However, functionalists reply that Searle begs the question when he asserts the whole system lacks understanding.

Some other critics of functionalism sustain that the problem for functionalism lies rather in the characterization of feelings, sensations, and other conscious mental states, since it cannot capture their distinctive “qualitative” or “phenomenal” character, which seems to be intrinsic and non-relational. This concern was at first discussed under the name “absent qualia” (see Shoemaker 1975). Another version of the argument poses the problem of “inverted qualia”. Recently, the discussion has been cast rather in terms of “zombies”: There might be two creatures functionally identical, but differing in their mental states, since one of them has a normal conscious life and the other none. This second twin would be the philosophical “zombie.” This possibility implies, to the non-functionalists, that the functionalist view is inadequate. Although such a criticism may also be pre-supposing the thing it is arguing for –, i.e., the existence of proper qualia –, the problem of conscious life, of consciousness itself, remains an ongoing controversy and probably represents the greatest challenge for functionalism in the philosophy of mind.

All advocates of functionalism are persuaded that intentional mental states can be adequately explained from a functional point of view. Some functionalists consider functionalism to apply also to qualitative mental states; other maintain it does not. So, it is possible to distinguish between strong and weak versions of functionalism. According to the strong versions, every mental state is completely constituted by its relations to inputs, outputs, and other mental states; no mental state exists therefore on its own. William Lycan seems

to hold this view. Weak versions allow for some, most frequently qualitative mental states to be basic and nonfunctional. That could be the view defended by Jaegwon Kim in his latest writings. Strong versions of functionalism are exposed in a higher degree to the criticism that functional characterization of mental states is holistic. Weak versions of functionalism do not succeed in explaining the mental in nonmental terms.

Furthermore, Ned Block (1978, pp. 310–314) says that all versions of functionalism are doomed to be guilty either of “liberalism” or of “chauvinism.” Theories are liberal when, building on functional equivalence, they (potentially) ascribe mental properties to things that do not in fact have them, for instance, to the entire population of China connected per radio among them and with an artificial body or robot, of which it plays the role of an external “brain” (this is also put sometimes as the problem of the “brain in the vat”). Theories are chauvinistic insofar as they falsely deny that certain systems have mental properties. And that happens whenever, in order to avoid liberalism, we include too much of human neurophysiology in our theory. The resulting functional description will not apply to (eventual) intelligent Martians, whose neurophysiology would probably be different from ours. All this has to do with the difficulty, not to say impossibility, of finding a description of inputs and outputs which is specific enough to avoid liberalism, yet general enough to avoid chauvinism.

Functionalism in the philosophy of mind offers interesting possibilities for the dialogue with theology. The most obvious regards, of course, the mind-body problem. Insofar as functionalism intends to be a non-reductive materialism, there is no a priori incompatibility between it and non-dualistic theological positions. It is not clear, however, whether functionalism can account for what we take to be the causal efficacy of mental states, an important point for any theological depiction of mind. Another thought-provoking proposal has been advanced by William Alston, who tries to capitalize on the principle of multiple realizability in order to show that “the same

functional concept of knowledge that *p*, or purpose to bring about *R*, could be applicable to God and to man, even though the realization of that function is radically different” (Alston 1985, p. 225). He aims to assert a certain degree of univocity in divine-human predication without compromising the otherness of God.

Functionalism in Sociology

Paolo De Nardis

Sapienza Università di Roma, Roma, Italy

Description

Although Functionalism was at one time considered the most typical expression of contemporary American sociology, it did not originate in the United States since we can find its earliest formulations in British anthropology.

In particular, Bronislaw Malinowski, a Polish-born British anthropologist, proposed the functional analysis as a solution to the tendency of interpreting social situations through intuition rather than through observation. The functional analysis, according to Malinowski, brings a scientific attention in the study of cultures that have to be different from the ones of observers. Therefore, according to this school of thought, before analyzing a social phenomenon that is typical of a given culture (an institution, a material object, an idea); you must first think of what function the phenomenon fulfills within this culture.

So the Malinowskian assumption of Functionalism is that in every type of civilization, every custom, every material object, idea, or opinion fulfills a vital function, meaning with “vital function” the contribution that each cultural path gives to the maintenance of the entire culture, that is, to the *integration* of the whole social system.

The core of functionalist theory is, therefore, the problem of integration.

Another anthropologist, Radcliffe-Brown, specifies, “the function of each recurrent activity is the part it plays in the social life as a whole and therefore the contribution it makes to the maintenance of the structural continuity.” He explicitly refers to Durkheim, according to which “the function of a social institution is the correspondence

between it and the needs of the social organism” and proposes to replace in this definition the word “needs” with the expression “necessary conditions for existence.” Let us see how he emphasizes the themes of cohesion and stability.

These issues (cohesion and stability) are the most evident limitations and targets of criticism that this school of thought has suffered. Among them, the most common is the claim that this system can only explain how to reduce or eliminate conflicts but it can never say why they came out or how and why they are increasing.

Another critique to Structural-Functionalism is that it is structurally related with the interests of the British colonial power for which these scholars worked.

It is also worth noticing that both Social Anthropology and the History of Sociological Thought focus their attention on normative and cultural aspects of social life rather than on economic or technical ones.

Hence, the method of Functionalism is to explain any social institution through the role it plays in the maintenance of society.

Talcott Parsons: From the Theory of Social Being to the Social System. The Functional Prerequisites

Parsons is perhaps the best-known representative of Structural-Functionalism, as the foundation of his sociology is the idea of integration understood in terms of cultural and normative aspects, although it has assumed different shades over the years.

Many European scholars including Malinowski and Weber influenced Talcott Parsons (1902–1979). His sociological orientation seems to be related to the practical needs of American society and it is not, as it has been argued by many, an ideological justification of the current economic, political, and cultural situation but rather – and above all – an attempt to identify the minimum requirements of integration in a society composed of different ethnic groups, with their traditions and cultures, in which integration appears as a need and a goal to reach. This

explains why cultural integration becomes the central problem of most of the American society.

In his essays, which were mostly produced in the period from the 1930s to the 1960s, he built a theory that claimed to be extremely general, and which sometimes has been called “The Grand Theory”. While Functionalism, especially in the medium-range theories held by Robert Merton, produces *ad hoc* explanations of everything that exists and happens in a particular time, Parsons aims at a general formulation of how all social systems work.

The Grand Theory has been very successful for a certain period of time, especially in the 1950s, but later has been heavily criticized by Neo-Marxism, by the Conflict Theory, and by the Microsociology theories like Symbolic Interactionism and Social Phenomenology. However, in the 1970s, the Grand Theory gained new fame, especially among German sociologists like Niklas Luhmann, Jürgen Habermas, and Richard Münch. More recently, some American sociologists led by Jeffrey Alexander have taken up and reworked on the Grand Theory in a revised form.

The Structure of Social Action (1937)

Parsons, opposing the positivist conception of action (understood in terms of a reaction to an external stimulation), tries to emphasize the voluntary aspects of action itself. He identifies some necessary elements for a social act that are listed below:

1. There is someone who performs the action (**the actor**).
2. Each action must necessarily have a “**finality**” (a future condition toward which the action is oriented).
3. Every action begins in a “**situation**” (whose lines of development can be different thinking of the situation toward which the action is directed).

In every situation, you can find elements that cannot be transformed by the Action (these are the **conditions**) and elements that can be transformed from it (the **means**). To choose the most appropriate means to achieve a goal, you need to conform to certain **rules**: These rules must be considered a necessary element of the

Action and are defined as the features that give shape to the finality.

According to Parsons, people do not only respond to stimulations but also try to conform their action to specific models, which are considered desirable by the actor and by other members of the community.

An action is a social action only when social purposes and standards are identified in a context of interactions that consider such finalities and such rules an integral part of the social situation.

According to Parsons, also Pareto, Durkheim and Weber arrived at the same conclusions. Even though the conclusions resulted from different ways and were based on different theoretical premises, this testifies the correctness of the voluntaristic conception of Action.

From Parson’s point of view, a society is possible only in the presence of finalities and common standards: In this perspective, the importance of the integration problem is clear.

Parsons tries to identify the key issues of the above-mentioned authors in order to build a general theory. From Durkheim, he revisits the concept of “heritage of common values” and the problem of integration as a moment and implementation of the so-called collective conscience, symbol of social solidarity.

From Marshall and Pareto, he revisits the idea of theoretical system and synthetic sociological theory supported by integrated values.

From Weber, he renews the concept and the theory of the social action.

We have Parsons structural-functionalistic theory by the confluence of the three elements (unhistorical by nature) which follow:

- Parsons takes Weber’s action theory (that in Weber itself moves from a methodological point of view to an empirical-inductive analysis) and gives it a new meaning that does not include all the historical elements; it has a meta-temporal connotation and therefore is taken from a deductive point of view.
- Durkheim’s heritage of common values is taken up in Parsons perhaps more aprioristic meaning; this could validate Luciano Cavalli’s theory on Parsons’s hostility toward philosophy of history and its background of irrationalism.

- The system concept is necessary to integrate these assumptions and to give some meaning and boundaries to Parsons's primary problem: "The Hobbesian question of order."

Because of these basic *aporias*, Parsons structural-functionalistic theory is produced as a crystallization of the theory of action, in itself partly unhistorical, in an undisputed and extemporaneous system of values, tending to the conservation of a social structure model. This happens because at its base there is an unhistorical concept of the theory of action becoming stiff as it is projected in an extra-historical and meta-temporal scheme of values.

The Social System (1951)

The integration problem is central and introduces the notion of **system**. Parsons says that since individuals perform their actions not in a random way but according to defined principles, as the agent has certain expectations from objects and from other individuals, you can talk about "personality system." System is as well the coordinated set of symbols that make the interaction possible and the network of relationships between people that do not act in an uncoordinated way but according to the positions assigned to them in this network of relations.

The cultural system, the personality system, and the society system have to be congruent with each other.

The culture, in particular, has the fundamental task of attending directly in the creation process of people's personality through the development of an internalization of rules and values in a society (where internalizing means to own and deeply assimilate them).

The internalization of cultural models guarantees order and gives stability to the system because all the people tend to behave in a way that conforms to society's expectations.

In every action there is a finality, a goal to reach and, of course, negative consequences to avoid: This is what Parsons calls a "cathectic" element; in addition, to conduct an action you must also have knowledge of the situation, and this is the "knowledge" element; finally you have to be able to pick out among the many possible

choices: This is the "evaluation" element. These three moments of the action can be distinguished only in an analysis but are indistinguishable in reality.

The individual's personality therefore can only arise in a context of social relations, which is able to develop a system of common signs and symbols, namely, in a cultural context.

The social system is thus defined in terms of interaction, but the interaction is taking place not between individuals, on the contrary in mutual relations among people acting in terms of status (social position of the agent) and roles (agent's activities related to his/her social position).

The status defines the position that a person occupies in a system of relations considered as a structure, regardless of the personality of the individual him/herself.

On the contrary, the role relates to what the subject does in its relations with others and it is typical of a certain status.

Example: I am a teacher (in society, since I am a teacher a certain position is assigned to me, regardless of whether I am a good teacher or not, or if I am more or less sympathetic, etc.) and I behave in a certain way during my work. I exercise my role (I will hold a certain behavior – as a professor – with my students); my students (as students and therefore regardless of their individual personality), for their point of view, expect from me a certain behavior, linked to the teaching profession.

According to Parsons, a person (*ego*) always has expectations in another person (*alter*), and the second person always has a set of expectations regarding the behavior of the first. *Alter*, however, is not a particular individual but is a "generalized other" (a concept already proposed by George Herbert Mead). *Alter's* reactions can also be considered like "sanctions" against *ego*, which consequently will tend to behave according to the related expectations and the specific roles they (*Ego* and *Alter*) perform. To sum up, expectations are linked to roles.

A single person in his/her life may occupy of a series of status and exercise the related roles.

The reciprocal expectations and sanctions related to the single roles create the *institution*

that is defined by Parsons as “a social structure unit, whose level is higher than the one of the role because it is composed by a plurality of interdependent role models and their own components.”

According to this definition, however, you cannot understand why and how in reality there exist several systems different from each other.

Parsons replied that the systems differ from each other following the alternatives of roles that the actor has to choose between: During the action, the actor receives a series of different alternatives that are always limited and defined in any way.

These alternatives are the “structural variables,” as follows:

- (a) Dilemma between reward and discipline: *affectivity – emotional neutrality* (need of choice between immediate satisfaction according to the emotional impulse or renunciation)
- (b) Alternative between private and collective interests: *egoistic orientation – altruistic orientation* (namely toward community)
- (c) Choice between universality and particularity: depending on whether the actor considers the object that is in relation with in the features that make it *common to an entire class or in its singularity*
- (d) Difference between construction and attribution: depending on whether the object is considered *for what it produces or what it is in itself, for its intrinsic qualities*
- (e) Quandary between specificity and diffusion: if the actor considers *some aspects of the object or its totality*

Parsons adds that these structural variables do not combine with each other in a random way but they follow certain rules, as they must be integrated into a system that has to be coherent in order to guarantee itself in time: For the survival of the system, some functional requirements have to be fulfilled. For example, in a system like the family, the roles have to be affective, particularistic, pervasive, and attributive, while in a company they will have to be universalistic, pervasive, profitable, and specific.

The modern industrial society is constituted by a system of universalistic, neutral, profitable, and specific roles.

Parsons’s theoretical conclusion is that every social system, in order to survive, must necessarily resolve a fundamental functional problem, defined as the “problem of allocation,” which has three characteristics: the allocation of the staffs (including the ones acting among the roles), the assignment of resources, and the attribution of gratifications.

Parsons deconstructs and reconstructs its structural variables with the aim of building different models of the possible “structural type,” which means different types of social systems and societies, and explaining his interpretation of the foundations to the various social sciences.

In his works that followed *The Social System*, Parsons abandons his explanation scheme based on structural variables and elaborates a “functional square” scheme where each frame represents a “functional prerequisite.”

The two dichotomous dimensions of internal/external very abstractly generate this scheme and means/finalities: Anything inside the system can be considered as operating or in the direction toward the inside or outside the system and can be either a mean or finality.

By crossing these two dimensions, we obtain the four quadrants that Parsons calls “AGIL”:

A for Adaptation, which is equivalent to adjustment, and it refers to the way the system maintains itself as a physical entity in connection with the material environment. Here we can find Economics.

G for Goal Attainment, which is the quadrant of achieving the objective. It deals with the fact that each system has a certain purpose and it tries to achieve it in relation to its environment – relating to the society, here we find Politics.

I for Integration, which is the quadrant by which the system keeps actively together its different parts – here we find all the institutions that promote social integration and the *corpus* of laws and rules under which all the members behave.

L for Latency, which is the quadrant of the latent model. It means that every system needs to

have some basic models: This quadrant involves all those institutions that produce basic cultural models and that transmit them to the individuals (by family, education, religion).

L and I are both subsystems within the system as they deal with the relationships inside the society: L are the means, I are the finalities.

A and G are both external subsystems: A is a mean, G is a finality (achieving the purpose).

Each of these quadrants can be divided in its own set of dials. Hence, you can go to the larger system rather than to the smaller one, as it is shown below:

In this way, Parsons's system provides a grid of the basic elements that each organization must realistically own. These functions are analytic (then, abstract) and apply to all the levels of analysis: individual personality, special organizations, institutions, communities, nations, or the whole world.

Furthermore, the different elements of the system operate together in order to ensure that people carry out their role in an appropriate way. There is, anyway, a hierarchy of control within the system, as we indicate below:

More generally, the system elaborates particular values; in the specific interaction situation, this general value is specified in certain norms, which are structured in roles, according to the position held by individuals in an organization. People guarantee the respect of norms attached to the various roles by applying sanctions, by

rewarding the ones who comply, and by punishing those who violate them.

To sum up, values are specified in norms, modeled in roles and reinforced by sanctions.

Robert K. Merton and the Middle Range Theories

While Parsons builds his “Grand Theory” as an explanatory system based on the functional analysis, with general and unhistorical characteristics, Functionalism in the United States takes very different directions from his position. The most important representative approach that differs from Parsons’s Functionalism is the one proposed by Robert K. Merton, who asserts the need for sociology to build “medium-range theories” that differ from large generalizations. These are not verifiable in empirical terms and differ from empiricism that only collects data without framing them in a theory.

These mid-range theories occupy an intermediate position between general theories of social systems (too far away from particular categories of behavior, organization, and social changes to provide an explanation of what is observed) and detailed descriptions of facts that are not minimally generalized.

The mid-range theories deal with limited aspects of social phenomena and refer to the summation of results from empirical surveys. Rather than considering only each single research for itself or building sociological theories not sufficiently supported by surveys, thinkers should build theories that are more than the single result of a research, but at the same time, they do not have to be unverifiable theoretical constructions.

Empirical research should be organized so that they, when you have empirical uniformities, when and if they are discovered, directly influence the theoretical system.

With this innovative position, Merton criticizes the first Functionalism by opposing a critique from within: He does not reject the interpreting key but the postulates (statements

that lie outside the empirical testing). Hence, he implicitly criticizes Parsons.

Merton identifies, in particular, three postulates of the first functionalists:

1. Postulate of Functional Unit: all the elements of a culture and all the social activities are functional to the whole social or cultural system.
2. Postulate of Universal Functionalism: every aspect of a social or cultural system plays a positive role toward social integration.
3. Postulate of Indispensability: each element existing in a society or culture is indispensable to perform a specific function as well as every specific function is essential to the whole system.

He criticizes them in the following way:

- (a) The fact that every society presents some integration is assumed. However, it is not true that all societies show the same high quantity of integration so that every action and every conviction is functional to society as a unit and at the same time is functional to the people who live in it.
- (b) You cannot say that everything that exists, because of its existence, has a positive role toward social integration.
- (c) It is not assumed that in every society you have the indispensable elements to perform certain functions, which may be performed by different elements or by way of the same elements always playing the same functions.

Without any doubt, Merton's conception of Functionalism admits the presence, together with integration factors, of dysfunctional factors: They tend to disintegration rather than to integration or they do not have any function. In addition, the functional analysis is considered a heuristic method.

Merton also introduces the distinction between manifest and latent functions: The former are wanted and recognized consequences of the action; the latter are the unconscious ones. However, Merton does not specify that the functional analysis makes sense as a specific method only if you search the latent functions, because it would not add anything new to the already known.

Merton tries to apply his medium-range theories to concrete societal problems, so he deals with issues such as anomie, reference groups, and sociology of knowledge.

Talking about anomie, Merton says that it comes from the discrepancy between the cultural structure of a society (which sets the goals to be pursued as well as the norms you have to follow in order to achieve these goals) and the social structure (organization of roles and status) of the same society. According to Merton, in this situation you can have different reactions. To properly analyze the problem you must make a threefold distinction and understand that: (1) on the one hand, in a social system, there are certain cultural goals, purposes, finalities, and aspirations that are based on the prevailing values of a specific "cultural structure"; (2) on the other hand, there are "norms" that prescribe the means that individuals can legitimately use for achieving their goals; (3) a third order of elements are the institutionalized methods arising from the concordance between the possible means for achieving goals and the opportunity to achieve goals in a way that does not disobey norms.

If a fracture occurs between these three variables, there can be deviant behavior in individuals or in social units that compose a particular social system.

The cultural structure prescribes the goals to be achieved: It may prescribe similar or different goals for all the individuals of a system; according to Merton, American society almost universally prescribes for its members the goal and the myth of success, mainly under the economic point of view.

This goal involves a wider sensibility and frustration for members of the lower classes, which have reduced access to institutionally approved means. According to Merton, it is just in the opening between means and goals (with the resulting tension that arises) that we may see a weakening of commitment in people toward both the goals that result from the values prevailing in a certain social system and the institutionally accepted means: You can assist at various degrees of anomie that produce

various forms of deviant behavior. The consequence can be acceptance or rejection, again depending on the circumstances, on cultural goals (finalities), or on means (institutionalized on norms as for analytical convenience “institutionalized means” and “norms” are inserted in a single category; the “means” category which refers to the social structure of the analyzed system).

Merton elaborates his famous synoptic mirror that refers to “an example of individual ways of adaptation.” Depending on the attitude toward the two variables (means and goals), we can have the positive values of “acceptance,” which are indicated by the symbol (+), or “rejection” that are listed with the symbol (–) or even the rejection of current values (the “status quo” values) and the substitution with new ones, which is indicated by the symbol (+/–). The scheme is described in the table below:

Ways of adaptation	Cultural goals	Institutional means
Compliance	+	+
Innovation	+	–
Ritualism	–	+
Refusal	–	–
Rebellion	+/–	+/–

- Compliance: when you accept both cultural goals and institutional norms.
- Innovation: when you give more importance to goals than to norms.
- Ritual: when you accept institutional norms to achieve certain goals, but you do not bother if you actually reach them or not.
- Refusal: when neither norms nor goals are accepted (artists, psychotics, homeless, alcoholics, drug addicts).
- Rebellion: when you refuse both cultural goals and institutional norms and you try to establish new goals and norms considering them most fair and valid.

Merton goes from his considerations on anomie to a wider analysis of the deviant behavior. He criticizes the psychoanalytic approach that explains it as an expulsion of too long repressed by the society biological impulses (Freud) and

asserts instead that it is related to certain socio-cultural structures: For example, the conflict between social and cultural structures is one of the common causes of deviance.

Merton therefore assumes that originally, there always is some correlation on cultural goals and on finalities that culture considers worthy of being achieved; he considers anomie a consequence of the impossibility imposed from the social structure to reach all the cultural goals, if not in violation of institutional norms. Thus, anomie is equal to lack of the above-mentioned norms. However, Merton fails to criticize the cultural norms proposed by society that are considered as uncritically given and accepted.

Talking about sociology of knowledge, Merton does not accept the European approach with all its great ideas of the world, of political theories, of philosophical guidelines, etc., and prefers to join, even if with some doubts, to his North American tradition, more thin and poor, that aims to study public opinion relating it to the mass media conditioning.

Merton’s choice to follow empiricism originates C. Wright Mills’s critique to “abstract empiricism” in general, where the word *abstract* means the poor consideration for the wider historical and social context of problems and the focus of attention beyond this context. Hence the risk of an empiricism which falls into ideology is generated.

Critiques to the Functional Analysis in Sociology

The functional analysis in Merton’s and Parsons’s expression, often called “Structural-Functionalism,” is one of the most discussed orientations in contemporary sociology. To be honest, the critique is more focused on Parsons than on Merton.

1. From many parts, Parsons was accused of considering only or mainly the issues of integration and social order rather than on problems of social change and conflict.

2. Dahrendorf criticizes that the emphasis on the internalization of order inside the individual leads Parsons to neglect the repressive and coercive power of society over individuals.
3. The research of a general sociological scheme is at the expense of the analysis of specific social-historical configurations.
4. Parsons sees the conflict as a disintegration factor: This is not always true; indeed, sometimes the conflict may also strengthen integration within the group and make it stronger in the fight with outside groups. In Parsons's defense, it should be noted that he looks for the minimum necessary conditions for the existence of a social system: The conditions that allow its existence although the presence of disintegration factors. Therefore, he cannot emphasize these factors, among which there should be conflict. It is also true that the conflict expresses itself only in the presence of a minimum legitimacy that allows the conflict to be recognized as it is between the opposite positions.
5. Some say that behind Parsons's "Grand Theory," there is an uncritical mirror of the prevailing North American society.
6. Alvin W. Gouldner tries to show how the different phases of Parsons's thought are in line with the changes occurring in American society: At the beginning – when he writes *The Structure of Social Action* – he operates in a political situation still dominated by individualistic and competitive values and is therefore linked to the idea of individual action as a fundamental element of society. When he writes *The Social System*, the emphasis moves from the individual will to the social system mechanisms through which the system maintains itself. With the advent of the Welfare State, Parsons abandons the idea of society as a system that individually regulates and maintains itself balanced and accepts the principle of State intervention: This means admitting that the State is the main source of power and initiative in society and the stabilizing factor of it. This goes against the basic principle of Structural-Functionalism that believes

that society naturally regulates itself not through the political force but through values shared among its members.

7. Parsons's mistakes are due to the conservative orientation of his sociological theory.

Other critiques consider Functionalism from a general point of view and are all designed to invalidate its formal-logic correctness:

- (a) Carl Hempel contests functional analysis's effective explanatory power since it can only dogmatically be assumed that, since a system only works under certain conditions that are satisfied only by certain elements, these elements are actually present in the system.
- (b) Hempel always criticizes the lack of precision in the terms used by functionalists.
- (c) Again, Hempel criticizes the inability of functional analysis to not arbitrarily make specific predictions because the hypothesis of a system that regulates itself is not sufficiently clarified.

The above-mentioned critiques work on a methodological level and could be joined to the ones, which, under a substantial point of view and since Parsons is still alive, stressed the risks of both an ontological hypostatization and an apodictic theoretical model.

Fundamental Theology

Paul L. Allen

Department of Theological Studies, Concordia University, Montreal, QC, Canada

[Foundational theology](#)

Description

Fundamental theology refers to a field within ► [Christian theology](#) in which philosophical, anthropological, scientific, and theological categories are deployed to mediate religious ► [faith](#) and the meaning of faith in culture. Theological reflection becomes a fundamental theology when it proposes a metaphysical or existential way of interpreting reality, including natural reality. In the twentieth century, following the rise of existential philosophy in Europe, fundamental theology became more prominent as a discourse about human history and the way that faith understands history. Since the 1980s, the dialogue between the natural sciences and theology has made an important impact on the character of fundamental theology, with more Christian theology written as a reflection upon nature and the subjects of scientific inquiry.

As a historical development primarily within the Christian tradition, fundamental theology refers to particular categories and concepts that are found on the edge of philosophy and theology. The term emerged as a more explicit form of discourse in the twentieth century. Prior to the mid-twentieth century, the discourse known in Christian theology as apologetics was the more popular approach to describing Christian faith in

terms of categories drawn from other disciplines. One classical source for traditional apologetics written from a Catholic perspective and published in 1910 is the four-volume *Dictionnaire apologétique de la foi catholique*. Fundamental theology is different from apologetics in its methodological clarity, its acknowledgement of cultural and religious pluralism, and its lack of a defensive attitude toward the findings of science.

Also referred to as “foundations” or “► [foundational theology](#),” fundamental theology uses specific interdisciplinary categories to identify and shape the meaning of theological doctrines and systematic theology. The categories of fundamental theology identify conceptual frameworks through which the diverse meanings of religious traditions are expressed, at least heuristically. The practice of fundamental theology nevertheless remains largely a Christian ecclesial and academic enterprise.

Fundamental theology is often equated with systematic theology or doctrinal theology. However, it is important to distinguish certain tasks that are specific to fundamental theology in order to avoid confusion. Philosopher and theologian Bernard Lonergan argues that fundamental theology is a set of tasks that follow from a personal commitment to a theological inquiry. Fundamental theology does not precede personal commitments. In this regard, fundamental theology resembles the more traditional discourse of apologetics. However, as Lonergan and others conceive it, fundamental theology should engage with the history of particular traditions of textual interpretation. There are two basic types of categories available to fundamental theologians, which are distinguished as general and special categories. General categories refer to those that are general in all human experience while special categories refer to those which arise from what Lonergan terms “religiously differentiated consciousness.” Special categories arise from Christian religious, moral, and intellectual conversion by which he means the ways that Christian faith guides and changes human living. Special theological categories are derived from the perspective of one who is converted to a fundamental outlook of love, a religious horizon that nevertheless allows that natural knowledge informs the ground of faith.

Categories are not merely normative objectifications which arise spontaneously. Foundational categories are authentic or worthwhile if they follow from transcendental method, a way of formulating theology on the basis of a normative way of understanding self-consciousness. Lonergan interprets human intentional consciousness as a compound set of four distinct levels: empirical, intellectual, rational, and responsible. ► [Self-aware](#) or self-transcendent intentional ► [consciousness](#) is the basic criterion for a theological method and hence the categories of fundamental theology. Fundamental theology needs to be rooted in the theologian’s own awareness of his/her recurring, dynamic experiences, understandings, judgments, and decisions as these are changed by religious love.

Karl Rahner is another theologian who concurs that fundamental theology is a way of apprehending both faith and the general form of human experience. According to Rahner, general human experience is already an experience and understanding of God because God’s creation of the world and of human beings renders all experience in the world religiously suggestive. He stipulates that “every ground of faith is also an object of faith, although the converse relationship is not true (Rahner 1982).” Rahner, along with Lonergan, shares an outlook that is termed “transcendental” for its resemblance to Kant’s philosophy, which stressed the conceptual frameworks from which all human inquiry (but not Christian conversion) invariably originate.

In contrast, British theologian Aidan Nichols specifies that fundamental theology addresses the question “What is faith based on?” a definition of fundamental theology that resembles apologetics. Leading twentieth-century Reformed, Protestant theologian Karl Barth also claims that all theological categories must be at the service of revelation and be firstly informed by revelation. Contrary to the transcendentalist viewpoint, Barth develops a fundamental theology that does not begin with human conceptual frameworks, whether philosophical or theological. For Barth and most evangelical theologians, God communicates a message which is witnessed by the Bible and identified with the person of Jesus

Christ. This way of understanding fundamental theology is rather different because of its insistence on the divine origin of all theological categories. For instance, the category of personhood cannot be developed apart from the revelation of the personality of God made known in the person, life, and death of Jesus Christ.

The different directions taken by theologians in the mode of fundamental theology suggest a divergence on two related questions – rationality and revelation. On rationality, there is a basic disagreement on whether a fundamental theology draws on a shared epistemology with that of other sciences and those of other religious traditions or whether Christian theology springs from a unique kind of rationality. Taking the former perspective, many twentieth-century theologians hold that critical realism is an epistemological outlook in which theology and the sciences affirm equivalent qualities of objectivity through the use of inference, imagination, metaphor, and judgment. But among those who adopt the latter perspective are those philosophers and theologians who adhere to “► [Reformed epistemology](#),” a view which claims that religious experience is sufficient by itself to justify certain beliefs so long as the believer’s mind is functioning well, a sufficient warrant for those beliefs to be rational and therefore plausible.

The other main issue in fundamental theology is revelation, which, according to Avery Dulles, can be modeled in five ways: as doctrine in itself, as history, as dialectical presence, as inner experience, or as a new form of awareness. Coherent with most of these models of revelation is the experience of conversion, which is at the very least understood to be an experience of oneself confronting a new and urgent reality. This experience of conversion is especially prominent in the famous work by William James, *The Varieties of Religious Experience*. As Barth’s theology shows, however, revelation is taken by theological realists to refer to an objective reality that does not need prior qualification or conceptualization within an originally human perspective.

Regardless of the positions adopted concerning either rationality or revelation, the terms of fundamental theology are not those of the explicit

interdisciplinary outlook of systematic theology, which aims to express an understanding of Christian doctrine in the context of contemporary questions and debates in church and society. Fundamental theology is also distinct from church doctrines since it does not aim to explain God with reference to concepts adapted for use by the Christian church. Fundamental theology is thus seen as a preface to the doctrinal task.

Self-Identification

The idea that theology is a science originates especially with Thomas Aquinas and the medieval scholastics in Western Europe. In the famous first article of his *Summa theologiae*, Aquinas asks whether a theological science ought to be considered in addition to philosophy in making enquiries about God. He answers his own question in the affirmative by saying: “Thus there is nothing to prevent another science from treating in the light of divine revelation what the philosophical disciplines treat as knowable in the light of human reason.” (*Summa theologiae*, Ia, q. 1, a., ad 2). Theology, like the physical sciences, proceeds from a set of principles to discover and express the properties of a certain object or set of objects. In this case, the object of inquiry is God, but unlike the philosopher’s sole resort to reason, Aquinas relies upon the sources contained in revelation, especially the principles he adduces from scripture.

More recently, Thomas Torrance, a theologian in the Reformed tradition, has sketched an epistemology whereby theological inquiry mirrors scientific inquiry by taking place along three levels. As science proceeds according to experience, theory, and an overall worldview, theology resembles this process by proceeding from worship to creedal formulation to theological elaboration. What renders theological science decisively different however is the way this threefold activity correlates with God as a threefold being. God’s revelation, revealed for us in mediated human form, is received and expressed by the church in three ways – proclamation, catechesis, and liturgy. In addition, Alister McGrath, a British theologian and scientist, has completed

a three-volume study of scientific theology that outlines a fundamental theology on the basis of key categories shared by scientists, notably the category of critical realism in epistemology.

Characteristics

Fundamental theology reflects on the fundamental justifications that are offered for interrelating the four sources of theology – scripture, tradition, reason, and (personal) experience. Whereas systematic theology is a subdiscipline that analyzes particular doctrines for their congruence or merit in light of scientific knowledge, fundamental theology reflects on the methodological presuppositions behind such proposals for congruence and the basis for establishing their merit. Whereas doctrinal theology purports to explain a theological reality on the basis of a theoretical explanation, fundamental theology provides the grounds for that explanation, the general horizon of meaning within which those doctrines are claimed.

Relevance to Science and Religion

Fundamental theology bears significant relevance to the field of science and religion inasmuch as fundamental theologians take an active interest in metaphysical and natural or scientific categories that form the basis for further theological reflection. Inasmuch as fundamental theologians are only interested in an interpretation of human history, the science and religion field is not implicated. The reliance upon a metaphysic and a philosophy of nature is often seen as counterintuitive for the theologian. For instance, many Catholic theologians have intentionally avoided metaphysical categories since Vatican II because for them ► [metaphysics](#) is associated strongly with the neoscholastic approach that was taught in seminaries prior to the 1960s. This approach strongly identified the philosophy of Thomas Aquinas with the natural categories of substance, accident, potency, and act, which were employed to determine the

scope and meaning of theological terms, including the Eucharist and moral doctrines. Evangelical Protestants, on the other hand, have avoided a natural metaphysics altogether until recently, out of deference to the principle of *sola scriptura* in theological method. Mainstream Protestant theologians, however, have relied on metaphysical categories, although their preferred categories have remained mainly historically oriented schools of thought, such as Paul Tillich and Rudolf Bultmann's reliance upon existentialist philosophy.

Since 1960 especially, theologians have been increasingly inspired by the work of philosophers of science Stephen Toulmin, Thomas Kuhn, Imre Lakatos and Michael Polanyi. Thinkers such as Ian Barbour, Robert Russell, John Polkinghorne, Arthur Peacocke, Thomas Torrance, Langdon Gilkey, Holmes Rolston, Wolfhart Pannenberg, Ted Peters, John Haught, and Nancey Murphy to provide conceptual frameworks for fundamental theological inquiries based in part on the work of these philosophers of science. As a consequence, more fundamental theologies are taking into consideration both philosophical and scientific perspectives in the orientation of theological concerns. Theology is being undertaken in new ways that place greater emphasis on the scientific significance of categories like “embodiment,” which is an important feature of the Christian doctrine of the incarnation. Embodiment thus mediates a theology of the Incarnation and the neuroscientific research into the relationship between the mind and body. This is a fundamental inquiry that serves the doctrinal task of establishing the difference between divine and human persons. Another category that receives some attention is that of the “research program,” a concept developed by philosopher of science Imre Lakatos and applied by some theologians as a methodological tool to describe how theology proceeds in a scientific manner.

Sources of Authority

The following English language academic journals devote significant space for articles in

the field of fundamental theology: *International Journal for Systematic Theology, Philosophy and Theology: Marquette University Journal, Faith and Philosophy (Society of Christian Philosophers), Modern Theology, Theological Studies, Gregorianum, Scottish Journal of Theology, Journal of the Evangelical Theology Society, and The Journal of Psychology and Theology.*

Ethical Principles

Fundamental theology is not guided by any one particular ethical principle, although it is certainly plausible to think of fundamental theology as a basic discourse of those who are committed to expressing the implied ethics of the Christian faith. Two principles, which stand out in the history of Christian thought and in biblical texts, are the principles of beneficence (aid and compassion directed toward others) and of reciprocity (do unto others as you would have them do unto you). A preethical or metaphysical principle with significant moral implications is the principle that human persons have unique ontological worth and equal value before God. Especially important is the tradition of this principle in the history of the interpretation of the Genesis creation narratives. Yet, personhood is affected by the empirical studies that are cited in the science and religion field on neuroscience and cognitive psychology. These disciplines, in a theological hermeneutic, can contribute to the understanding of persons as made in the image of God (*imago dei*). The moral principles of beneficence and reciprocity are deeply impacted by evolutionary psychology studies in kin selection and altruism.

Key Values

The key values of fundamental theology are unity and coherence. The value of unity is implied through the commitment of fundamental theologians to categories that take into account concepts and historically identifiable priorities from the four theological sources of scripture, tradition, reason, and experience. Reason becomes somewhat more

prominent through the necessarily clarifying role of philosophy in framing fundamental theological discourse. Coherence is a key value for establishing the epistemological horizon and metaphysical grounds for doctrinal explanations and systematic theology, which is dedicated to a correlation or comparison of doctrinal/creedal statements in light of other knowledge of the world.

Conceptualization

Nature/World

Nature is conceptualized by many fundamental theologians as one pole within a dialectical understanding of reality, with God as the being who is the author of nature. Fundamental theology is most interested in categories that deal with God and God's communication to and in the world. Yet, nature is seen as playing a key role in describing what God is like. For fundamental theologians such as Thomas Aquinas, features of nature assist in helping us understand God analogously and through telling us what God is not like (*apophatic* theology). In one of Thomas Aquinas' arguments for the existence of God, the good that is known in nature can help us understand the goodness and perfection of God. However, the finite limits of nature aid us in understanding the infinity of the eternal God.

Beyond analogous language, nature is also understood as having its own structure that fundamental theologians deploy in their efforts to conceptualize God from the standpoint of creation, a genre of fundamental theology that is identified as natural theology. In natural theology that is affected by the science and religion field, the concepts of emergence and creativity, complexity science, and the disciplines of cosmology and mathematics bear more weight in communicating the order and patterns that one would expect to see in the world if there is a God.

Human Being

In order to present a portrait of fundamental anthropology, theologians adopt certain motifs or concepts to account for why human beings are spiritually and religiously oriented. Karl

Rahner developed the idea that human beings are “the hearers of the Word.” That is, human beings are created with the precise relational, communicative, and value-seeking capacity to which God’s revelation is a response. Going on the paleoanthropological record, other thinkers beginning with Teilhard de Chardin and more recently, J. Wentzel van Huyssteen, have shown that human beings are inherently religious beings. Inherent religiosity is linked with symbolic communication and the moral disposition to expand an evolutionary epistemology that does not reduce our cognitive and emotional capacities to being survival mechanisms.

Person

See “[Ethical Principles](#)”

Life and Death

Fundamental theologians see life as a creation of God and the gift that God has given in anticipation of a response. Such a response is solicited from humanity in the form of faith. Death is thus understood not as the end but as the potential passage to eventual new life. Fundamental theology already has recourse to the general category of hope and cognate concepts to initially express what is meant by the traditional doctrine of heaven. This new life is characterized as a corporate reality by most contemporary Christian fundamental theologians. This corporate aspect of new life is seen as a corrective to many historical and contemporary individualistic interpretations of heaven or afterlife.

Reality

Fundamental theologians understand reality to be grasped as a given that exists prior to the human experience of it and as the spatiotemporal work of an eternal God. But in light of the methodological success of the natural sciences since the seventeenth century, fundamental theologians increasingly view the selection of general and special theological categories in critical realist terms. Reality is assumed to be given but known, as the philosopher Immanuel Kant emphasized, through our own categories and conceptual frameworks.

Knowledge

Fundamental theologians view their task as the establishment of grounds for doctrinal and systematic theological affirmations. Knowledge in this view entails the employment of analogies, inferences, metaphors, interpretive tools, allegories, and moral frameworks in order to set out the basic categories for fundamental theology. This diversity of methodological tools differentiates theology from the natural sciences, which rely on a complex set of deductive and inductive inferences, experimental, and verification techniques. While the frameworks constructed by the mind are the only subjective means to knowledge, the authenticity of that subjective mediation is a guarantee of the achievement of objectivity that is, in turn, subject to ongoing revisions at the level of fundamental categories, doctrines, and systematic theology.

Truth

Seen through the prism of Pontius Pilate’s question to Jesus in Matt. 18:38 “What is truth?” Christian theologians have understood truth to be a fundamental category with which the claims of Christian faith are concerned. Following the debates over critical realism and objectivity in theological knowledge, fundamental theologians believe that truth claims are made in doctrinal statements. However, hermeneutical, historical, and linguistic critiques over foundationalism ensue. The problem of foundationalism raises the critical realist debate which is exemplified in the statement: Are we granted some immediate access to the truth of particular states of affairs? Following the tradition of Friedrich Schleiermacher, the answer is no because the truth of any religious claim is a function of personal interiority, of religious emotions, and of self-consciousness. Following the critical realism of fundamental theologians in the Thomist, Reformed, evangelical traditions, and among those influenced by the science-theology dialogue, truth is expressed by Christian beliefs even though the linguistic expressions of Christian faith in beliefs and doctrines undergo developments in tandem with cultural developments.

Time

At issue here is whether we understand temporality as a part of God. Traditional models of God place eternity and time as conceptually dialectical. Karl Barth builds on this opposition in his own “dialectical theology.” Augustine and Thomas Aquinas concur by describing God’s eternity as timeless. On the other hand, beginning with the Cappadocian Fathers in the early church, other traditions in Christian theology have stressed the temporal character of the Christian God, going on the presentation of God as a trinity of persons. On this reading, change, relation, incarnation, and spiration connote a temporal character to God’s being. Thus, some fundamental theologians speak of God’s eternity as the “fullness of time.”

Rationality/Reason

See “[Description](#)”

Mystery

The categories of fundamental theology are intended to help us grasp the mystery of God as an objective reality in its many facets. Mystery is one of the basic fundamental theological categories, and Augustine speaks of it from its basic anthropological perspective when he claims that humans are a mystery unto themselves. With the human analogue as a starting point, fundamental theologians speak of the mystery of God. Mystery is further taken as a conclusion to cognitive psychological studies from which theology may begin its reflection on the human experience of transcendence. Bernard Lonergan approaches the mystery of God by speaking of the mystery that is experienced in our encounter with the realm of transcendence, a conscious experience. Paul Tillich, by virtue of his method of correlation, sees mystery, mystical experience, and transcendence as the ties that relate general human existential categories with special Christian categories, understood as symbolic.

Relevant Themes

Three themes are especially critical for a fundamental theology in the context of the

science-religion discourse. The first is the question of the “*laws of nature*.” For fundamental theology, this question has become intensified ever since philosopher David Hume expressed twin doubts over whether physical phenomena are actually caused and whether miracles exist, preferring to think of miracles as implausible violations of a law of nature. To this day, the question of miracles persists among fundamental theologians as possible events conceptualized as exceptions to the regularities described by the laws of nature. This view lies contrary to the consensus among many western Protestants since Schleiermacher (d. 1834) that a miracle is “simply the religious name for event.” What matters for advocates of this view is neither the objective character of laws of nature nor the grounds for establishing whether those laws have been violated but rather the subjective perspective on nature taken by individuals. Yet, a resolution of interpreting miracles depends, in fact, upon a prior resolution of the meaning of the “laws of nature.”

Throughout most of its history, Christian theologians have contested that the reality of nature’s laws matters as a form of testimony to God’s creation. Beginning in the Middle Ages within Christian theology and among Islamic philosophers as well during this time, the question arose whether it was fitting for God to intervene in the natural processes of creation which God established in the first place. Theological voluntarists have affirmed the distinct possibility of God being one who is able to willingly intervene. William of Ockham (1285 ca. – 1347), through his opposition to Aristotle and Thomas Aquinas’ theology, attacked the idea of things having common essences. Instead, he substituted the natural independence of natural laws with the idea of God’s total omnipotence and freedom. The world, as a created reality, is dependent upon God’s will, not independent natural laws. Today, the theological affirmation of the laws of nature is set against the view that nature and its laws constitute a necessary reality opposed to God’s power. Whether through statistical probabilities, evolutionary chance, or other natural process which depend on lower order physical laws, fundamental

theologians such as Keith Ward see natural laws as the structures within which God's purposes are forged. Miracles are thus allowed because they are seen not as violations but rather as transformations of natural laws, foreshadowing or echoing the spiritual foundations of created reality.

A second theme that characterizes the work of fundamental theology is the issue of *divine action*. Robert J. Russell of the Center for Theology and Natural Sciences (Berkeley, CA., USA) is a leading proponent for the view of God as an objective, noninterventionist actor in nature and history. Divine action is understood to be problematic not in the sense of God's general *providence*, as a creator God, but in the sense of God's special providence, which is a way of speaking about God's ongoing relationship and communication with the creation. The view that God is an objective actor whose action is still noninterventionist is meant to counter the prevailing influence of two older views about God's action in the world: (1) that God's action is objective and therefore intervenes in the laws of nature or (2) that God's action is subjectively felt by humans only and God does not need to intervene in the laws of nature. Both of these older views are discredited to the extent that they each presuppose a mechanical, deterministic portrait of the laws of nature.

Interpreting the laws of nature is widely seen as ultimately important for fundamental theological categories. Implied with regard to whether God acts in the world are the fundamental categories of communication and revelation. If God is communicating with human beings in the world through the biblical witness, the person of Jesus Christ, and so on, does this communication simply bypass biological, chemical, and other laws of nature? Does this communication imply an objective intervention in the laws of nature (option 1), is it merely subjectively felt through the mediation of nature (option 2), or is God's communication made possible by the laws of nature while being both objective and noninterventionist (option 3)?

While no consensus over divine action in or through the laws of nature yet exists, there is general acknowledgement of a related problem concerning divine action, a problem which arises on the assumption of a causal closure within the

world's natural processes. On that assumption, there is a sharp choice to be made between a compatibilist and an incompatibilist view of the relationship between the laws of nature and divine action. A compatibilist view sees God as working through nature, on which science can give an account, provided that this account is understood as pertaining to secondary causes, not the ultimate "primary" cause of the world and everything within it. Thomas Aquinas provides the most significant compatibilist account of divine action based on his inheritance of Aristotle's philosophy of nature. On the other hand, an incompatibilist view stipulates that God's action in the world be given some kind of evidential demonstration. An incompatibilist sees an inherent potential conflict between the claims of divine action in the world and the scientific web of explanations for the world.

A third theme that has appeared in the work of a number of fundamental theologians is the concept of *process*, a category which made its initial important impact through the work of philosopher *Alfred N. Whitehead* and later, theologian John Cobb and then *Ian Barbour*, who is regarded as an early founder of the science-religion dialogue in the United States. Barbour has been a strong advocate of the category of process, conceived as a form of society or network within which God is a cosmic leader. Process is deliberately viewed as an alternative way of modeling God and nature in contrast with the hierarchical and monarchical models that characterized traditional Christian models for God and nature. Accordingly, Whitehead termed God as "the poet of the world" (Whitehead 1978). Charles Hartshorne is another process philosopher whose concept of God has been influential among fundamental theologians, especially in light of his analogy for the God-World relationship as like that which exists between the human mind and the body. The basic intuition of process theology in this regard is that God is internal to the natural process of the universe, an idea which provides science and religion with a means for articulating the overall coherence of nature, history, and God's personal revelation. Critics on the other hand claim that process is neither amenable

to science nor to theology, or at least classical theology, and so it is a category that cannot be verified or falsified according to either scientific practice or theological tradition.

[Theory of games](#)

Description

Game theory is a set of mathematical models and techniques developed to analyze interactive decision processes, to identify optimal strategies, and to predict the outcomes of these interactions. From the beginning, game theory found interesting applications in the social sciences, especially in economics, but in the warfare too. The seminal work in this field is debt to John von Neumann and Oskar Morgenstern. In 1944, their book *Theory of Games and Economic Behavior* established game theory as a field. During the last two decades, the advances in this discipline have been recognized with several Nobel Prizes in Economic Sciences. In 1994, Nobel Prize was awarded to Nash (Nash equilibrium), Harsanyi (Bayesian games), and Selten (subgame perfect equilibrium). Aumann and Schelling got the 2005 Prize for having enhanced our understanding of

cooperation and conflict through game theory, and in 2007, Hurwicz, Maskin and Myerson obtained the Prize for their contributions to the mechanism design theory and, in 2012, Shapley and Roth were awarded for his work, theoretical and empirical, respectively, explaining the market behaviour.

Self-Identification

Science

Game theory is an area of mathematics and thus has self-identified as a formal science. This classification is a consequence of the debate under which some thinkers admit mathematicians are scientists for whom the experiments are the mathematical proofs while others do not see mathematics as a science since it is not necessary to experimentally test the theories, as formulas and theorems are logically obtained from a set of axioms. The knowledge of the theory of games is similar to empirical sciences in that it involves a systematic study of a discipline: the interactive decision process, in this case. But it differs because it uses a priori rather than empirical methods. Nevertheless as a formal science, it is vital to empirical sciences. The advances in game theory have lead to major advances in natural and social sciences: economics, sociology, politics, biology, philosophy, and psychology and even in how people think and act.

As it is said, game theory was initially developed to understand firms, markets, and

consumers' behavior, but its use has expanded. Now it is applied too in political science (social or public choice, fair division, war bargaining, political economy), biology (evolutionary game theory, fighting behavior, biological altruism), philosophy (interactive epistemology, ethics, psychological egoism), computer science (interactive computations, multiagent systems, online algorithms, computational complexity), and logic (game semantics).

Religion

This discipline is, within mathematics, a formal science devoted to analyze the conflicts in which each actor's success depends on the choices of the others. The aim of game theory is to tell us what the best strategies are to produce a positive outcome in a conflict situation. For many individuals, religion is useful in the sense that they follow the religious norms to conduct themselves in order to live positive lives. In recent years some scholars have thought that, if game theory is really valid, it must necessarily have some connections between the solutions proposed by the theory and the moral behavior derived from trusting in God.

Characteristics

Game theory differs from the other areas of mathematics in several aspects.

First, game theory has a significant role to play in almost every branch of science and for many scholars can be considered the language for social sciences. Moreover, scientists have two different points of view using game theory. Those (specially economists) who interpret game theory in terms of revealed preference theory regard game theory as the part of mathematics that permits to model process with the objective of maximizing a utility function. Other scholars look at normative aspects of game theory which, for them, provide an explanatory account of strategic reasoning. In this case, the game theory logic is used to recommend several actions as the rational ones.

Second, game theory is a way of thinking that is distinct from the modes of thought in other

areas of mathematics. Just as understanding spatial relations motivated geometry or to understand the uncertainty motivated probability, the theory of games is born to understand the complexity of the interactions among individuals and the economic behavior. Nevertheless, its use nowadays has expanded. Moreover, game theory is a distinct way of thinking within mathematics and economics. Compare the intuition of game theory in the optimization process with the traditional approaches. Because of this special intuition, it generates tools and techniques that are relevant to other areas of mathematics, economics, and sociology or philosophy.

Relevance to Science and Religion

From Pascal's wager, game theory is interested in science and religion. The Pascal's wager belongs to decision theory, a branch of game theory, and gives the different outcomes of the strategies of the atheist and the believer in mathematical terms. It is the most famous Christian apologetic game. But game theory is a powerful way of thinking to be used by religion apologetics:

- Prisoner's dilemma has an outcome that agrees with the traditional Christian morality.
- Religion responses to reality and morality can be explained by game theory and evolutionary psychology in terms of strategic behavior.
- There are many scholars that use the rational choice in economics to understand religious behavior.
- The mathematics of evolutionary game theory helps us to study the emergence of altruistic behavior, forgiveness, and unselfish love.

Sources of Authority

The sources of authority in this discipline are mathematicians and economists interested in developing a rationality useful for the analysis of interactive behavior. In 1838, Cournot in his book *Recherches sur les Principes mathématiques de la Théorie des Richesses* (*Researches into the Mathematical Principles of*

the Theory of Wealth) considered the problem of duopoly and introduced a solution that is a particular case of the concept of equilibrium defined by Nash a century after. In 1938, Borel in *Applications aux Jeux de Hasard* (*Applications to Hazard Games*) proved the minimax theorem for two-person zero-sum matrix games (only for the case of symmetric payoffs). Nevertheless, it is considered that the foundational work in game theory is debt to the mathematician John von Neumann. This work culminated in the book that he wrote with the economist Oskar Morgenstern, *Theory of Games and Economic Behavior* (1944).

The 1950s was ages in which game theorists developed many interesting contributions: the prisoner's dilemma (this game has fascinated them and scholars of different disciplines from its definition), the Nash equilibrium, the concept solution for cooperative games or TU games known as the core, the extensive form of the games, the repeated games, and the Shapley value (the most famous point solution for TU games). Moreover, the first applications to political science and philosophy appeared.

In 1965, Selten introduced a refinement of the Nash equilibrium concept, the subgame perfect equilibrium.

Later, he refined this new idea introducing the trembling-hand perfect equilibrium as well.

Harsanyi, in 1967, introduced the concepts of complete information and Bayesian games. Nash, Harsanyi, and Selten obtained the 1994 Nobel Prize.

Another great step was done in the 1970s when Maynard Smith applied game theory to biology introducing the evolutionary games and the concept of evolutionary stable strategies. At this time, the ideas of common knowledge and correlated equilibrium appeared.

In 2005, Schelling and Aumann became Economics Nobel laureates: Schelling, because of his work in dynamic models, and Aumann, because of his contributions to the equilibrium theory.

In 2007, Myerson, Hurwicz and Maskin obtained the Economics Nobel Prize *for having lead the foundation of mechanism design theory* and, finally, in 2012, Roth and Shapley were

awarded for their contributions to explain the market behavior from a game theoretical approach.

Ethical Principles

Even in its origins, game theory was based on individualist ideas, especially in the environ of zero-sum games but also in the definition of the value for cooperative coalitions in a TU game; today *Game Theory has already contributed to the study of collective choice and of certain kind of "fairness" ; it may be helpful in clarifying those ethical constrains that affect people's expectations about each other and in working out the social-behavioral implications of different ethical systems. Examples are lying, breaking promises, coercive threats and the possible social inefficiency of selfishness or altruism* (Shelling 1968, page 34).

Considering the influence and use of game theory in ethics, it is possible to distinguish three types of contributions in the literature:

- (a) The contribution functionalist under which the function of morality is analyzed. The consequences (problems, paradoxes, and dilemmas) that would occur in the absence of morality are described and, simultaneously remedial to avoid them, are prescribed.
- (b) The second one comes from the evolutionary game theory and concludes that morality is the unintended side effect of the interaction of agents, emerging as an evolutionary stable strategy from a series of repeated interactions between small groups of actors.
- (c) The so-called contractarianism that uses bargaining theory to establish the social contract theory under which rational agents agree with norms and political institutions under suitable conditions.

We cannot avoid mentioning the implications that the results of game theory have on the behavioral recommendations of moral theorists. As there exist in many models and especially in repeated games a great variety of equilibria, game theory has reason to contradict moral theorists that claim generality, universality, and

uniqueness for their specific recommendations. Moreover, in any population we can assume and accept determinate mixes of individuals with different behavioral dispositions. This is the framework in which strategies (and particularly the ethic ones) evolve.

Finally, a classical criticism to the relation between game theory and ethics is that the man proposed by game theory is completely characterized in his decisions by his ranking of preferences over outcomes, and thus, moral distinctions have no place in this portrait.

Key Values

The key of game theory is to analyze the behavior of actors in conflict situations, helping them to adopt useful strategies. The normative point of game theory prescribes efficient strategies that in many situations lead to an ethical behavior. It is possible to say with confidence that game theory is the most important tool whenever analyzing situations in which the best action of each actor depends on the best actions of the rest.

Besides its initial conception as a method to thinking of conflict situations, today its applicability has spread to a wide set of areas as political science, philosophy, logic, or biology and including models not only for human behavior but also for nonhumans as computers or irrational animals.

Conceptualization

Nature/World

Nature is conceptualized as the biological foundation of our planet in which all processes occur. World compresses the material space where all interactions take place, and thus, it is the framework in which actors interact and in which theory of game models can serve to explain or to prescribe player's behavior.

Human Being

The human being is considered individually rational and having the capacity to take decisions

that can involve to distinguish between the outcomes of individual and collective rationality, selfishness, and altruism.

Life and Death

Life is conceptualized as the presence of physical functions. These functions appear as an optimizing process based on the fitness. Death is not conceptualized in game theory.

Reality

Reality is considered as the environment in which interactions occur and actors develop their strategies and obtain their outcomes. The reality is then viewed as something strategic where all players involved try to optimize its rewards.

Knowledge

Knowledge is the amount of information the actors can retrieve as a consequence of their participation in the interactive conflicts. It is identified with information and can be partial or complete. The concept of information, the different possibilities that are given to actors, and the changes that are introduced in games are of extreme importance in the description and prescription of behavior in game theory.

Truth

Truth is not seen in game theory as a supreme concept but as a relative one. Truth is the reality of each interaction, the mathematical model used to describe it. But this model changes if the environment changes too. Nevertheless, in all cases it used the truth of mathematics to obtain the solution or solutions that are considered rational.

Perception

Perception is conceptualized as the information that actors receive from the actions taken by other actors. Sometimes players can know the strategy of the others, and sometimes they only perceive the outcome corresponding to the use of this strategy. Of course, the perception is related to the information that players have, and as a consequence, the reality is assumed to change completely as a function of the perception and information. Some optimal behavior with certain

type of perception can be a disaster if the information differs. Recently, different game theoretical models, in which misperception is considered, are developed to analyze the behavioral implications and even the possibility of evolutionary advantage.

Time

Time too plays a central role in game theory. Interactive processes change deeply on the basis of the conceptualization of time. Things can be very different if players take their decisions simultaneously or sequentially or when the game is a static one instead of a repeated-in-time one. Also different models are developed in which time is discrete, but others are considering continuous time.

Consciousness

The consciousness in this discipline coincides with the perception and information that players have of the others and others' actions.

Rationality

At its origins, game theory was created assuming a very high rationality of the actors involved in conflicts of interests. Agents then act with the aim of maximizing their outcomes. As in the real world, sometimes this behavior leads to conflicts with the collective behavior (rationality) appearing paradoxes or dilemmas such as the prisoner's one. On the other hand, experimental results in applied sciences have shown that the behavior of real human subjects cannot be described under this strong rationality. In experimental situations, the lack of transitivity of preferences and some behavior that ignores the typical assumptions involved in the solution of games is relatively frequent.

From the 1970s, the evolutionary game theory developed by Maynard Smith successfully explains the stability of certain behavior of irrational animals. Moreover, this evolutionary game theory has expanded its applicability to topics that include altruism, moral and social behavior or signaling systems, and private property conflicts, to name only a few. So we can conclude that the original assumption of actors'

hyperrationality is not now as central in game theory as in the past.

Finally, different models assuming subjective rationality are considered in game theory. Under subjective rationality, agents are assumed to choose the behavior that maximizes their perceived payoffs.

Mystery

Mystery in game theory is this type of dilemma or paradox that can describe problems in conflicts but for which a normative prescription is of very difficult implementation. Typical examples are the prisoner's dilemma (individual vs. collective rationality), the mystery of Talmud (division of insufficient funds of a dead man among his creditors), and the battle of the sexes (how a man and a woman can agree in the case of opposite interests).

Relevant Themes

A critical aspect of game theory regarding "science and religion" is to explain the religious responses to reality. Science and religion have often been placed in the opposite sides of rationality spectrum. Nevertheless, in recent years the former tries to approach the latter, explaining its existence. So, some scholars are interested in taking into account the hypothesis of God refusing the very famous answer of Laplace to Napoleon when this one showed his surprise by the fact that a large book on the system of the universe was written by Laplace having never mentioned its creator: "I have no need of that hypothesis." Experiments are done to prove that, in general, people trust more in those who believe in God, to establish the links among different religions and the relation between the level of cooperation and whether such cooperation brings collective benefits not only to the religious community but to those outside it. Based on the results of these studies, many scholars argue that religion promotes fitness as a consequence of within-group collaboration, a typical idea of evolutionary games.

Wright (2009), using a game theoretical point of view, argues that religion is a rational response to nonzero encounters, those in which all actors can win. Primitive men tended to view worthy of moral

consideration only the members of their tribe. As the cooperative interactions expanded to other clans, the moral considerations affect different ethnic groups, then nations, and finally all human beings.

In sum, the use of game theory, in this context, tries to emphasize an economic interpretation of the religious behavior: people want rewards from low costs.

Games, Computer

Evan Drumwright
Computer Science Department, The George
Washington University, Washington, DC, USA

Related Terms

[Computer science](#); [Console games](#); [PC games](#); [Video games](#)

Description

Computer games are art forms, which encompass nearly all forms of interactive

entertainment using a computing device as a medium. Most recent developments are centered around the introduction of new genres and new forms of play made possible by advancing technology. Relatively new genres include *first person shooters*, *simulation games*, and *serious games*. The most significant recent development has been the introduction of motion sensing game controllers, which have made new forms of game play possible by allowing the game to act using the player's movements.

Self-identification

Science

Computer games are art forms – they are designed to trigger emotions such as happiness, anger, and fear – and therefore, do not identify with science. Computer games do utilize science from computer programming, psychology, and economics, among other disciplines, in their development.

Religion

There is some relationship between computer games and religion. Many computer games – role-playing games, in particular – include references to religion. Computer games occasionally feature religion in a central role; the active subdiscipline of *Christian video games* is a product of the intersection of computer games with religion.

Characteristics

As art forms, computer games are inherently distinct from the majority of other disciplines in Computer Science; *Fractal Art* (i.e., creating fractal artwork with computers) is a similar distinctive discipline that combines art with Computer Science. Computer games are also interactive by nature (unlike Fractal Art), and nearly universally contain components for fun, learning, or both.

Relevance to Science and Religion

Computer games may see itself relevant to the interaction between science and religion when a computer game incorporates this theme into the play. A recent game that includes this theme is *Spore*.

Sources of Authority

Computer game development is a relatively new phenomenon. There are, as of yet, no authoritative journals dedicated to computer game development. However, the Game Developer's Conference (which concentrates solely on video games) presents advanced techniques used to create the latest games. This conference, which is recognized as the largest annual gathering of video game developers, was first held in 1988. A European version of this conference – Game Developer's Conference Europe – was formed in 2001.

Several trade publications also provide information for game developers. The most prominent print and online publications in this area are *Game Developer Magazine*, *Gamasutra*, *MCV*, and *GamesIndustry.biz*. The oldest periodical in this area, *Play Meter*, focuses on the coin-operating gaming industry, but also contains news of interest to game developers.

Video game universities also serve as an authority for video game development. Such “universities” consist of both dedicated institutions (e.g., DigiPen Institute of Technology, Full Sail University) and schools within traditional universities (e.g., “The Guildhall” at Southern Methodist University, the Interactive Media Division at the University of Southern California).

For consumers, periodicals and websites are the sources of authority on this discipline and typically contain reviews of video games, rumors of impending video game releases, and publicity for games that are soon to be released. The consumer-oriented websites

can be grouped into blogs and online-only periodicals.

Ethical Principles

Computer games require significant production effort, and their development is typically restricted to commercial entertainment studios, large academic laboratories, and government institutions. Adherence to ethical guidelines is generally not of interest to the institution that develops the game; financial and public relations interests are dominant. The lack of ethical guidelines occasionally results in games like *Muslim Massacre* (Clarke 2008) and *RapeLay* (Alexander 2009), which feature themes that are distasteful to the general public. The issue of ethics within computer games is being studied by some scientists (Sicart 2009).

Key Values

As art forms, computer games are capable of representing the most magnanimous and also most base human behavior; as such, there are no values intrinsic to the discipline.

Conceptualization

Nature/World

Nature has no discipline-specific definition, so the definition remains “the non-man-made world around us, including plants, animals, and geography.” A *world* is the player's environment within a video game (in the context of many adventure and role-playing games), a planet (in the context of space-faring games), or both.

Human Being

Within computer games, the term *human beings* is typically used to distinguish players of the species *Homo Sapiens* from other – typically mythical – anthropomorphic creatures, including dwarves, elves, and giants.

Life and Death

Life may be a commodity in the genres of action and shooter games; three to five “lives” – which are expended when a player “dies” by taking too much damage from enemies, traps, falls, etc. – are typically allocated to the player in games that use this system. Origins of life are not considered, unless this component is made a theme of the game (as in the game *Spore*).

Reality

Reality, in the context of computer games, is typically the player’s real environment (external to the game).

Knowledge

The sum of what is known (no discipline-specific definition).

Truth

Accuracy, a verified fact, or conformance to reality (no discipline-specific definition).

Perception

Perception is the understanding of sensory information by humans; the computer game acts as a medium between the virtual environment and the human, so the game is able to skew the human’s perception of this environment.

Time

Time is the measurement of the number of repetitions of a cyclical event (e.g., the oscillations of a crystal). In the natural world, units of time and time of day are typically determined using the speed of the rotation of the Earth as a standard reference. Within computer games, time is generally not synchronized to the actual time of day (flight simulation games can be an exception); time within computer games may be scaled such that more or fewer units of time pass within the same period as passed in the external world.

Consciousness

In the context of some action and shooter computer game genres, a player’s human character may lose consciousness (illustrated

by an inability of the player to perceive the environment) if the character is injured too heavily (e.g., the recent shooter game *Killstrike*).

Rationality/Reason

Good sense and sound reason, a sound motive (no discipline-specific definition).

Mystery

In the context of computer games, *mystery* is a component of some adventure games (e.g., *Myst*).

Relevant Themes

Computer games have the ability to engage religion, in both positive and negative ways, via religion’s portrayal within the game (e.g., Clarke 2008). Respect for religious beliefs has generally been treated carefully by computer game developers in the relatively short history of computer games.

Geography in Islam

James E. Montgomery
Middle Eastern & Islamic Studies, University of
Cambridge, Cambridge, UK

Related Terms

[Astronomy](#); [Cartography](#); [Chorography](#);
[Cosmography](#); [Geodesy](#)

Description

The textual consolidation of Muslim geographical knowledge began in the ninth century (under the patronage of the Abbasid dynasty, r. 750–1258) and persisted until the demise of the Ottoman Empire. This fluid and compendious body of knowledge, which included geodesy (al-Biruni [d. ca. 1050] measured the length of a degree of latitude); cartography, including an early map of the Earth made for the caliph al-Ma’mun (r. 813–833) considered superior to those of Ptolemy and Marinus of Tyre; astronomy; topography; and chorography, came to be known in Arabic as *Jughrafiya*, a calque from Greek. The verbal description of regions proved a perennial genre, concentrating on either the provision of global accounts or confining itself to the dominions under Muslim sovereignty. Its origins were, as the textual commentary to the world maps, the nucleus of the Islamic geographical tradition, and its appeal was due to the importance to Muslims of the annual pilgrimage to Mecca, accounts of which by the twelfth century developed as a recognized genre (*rihla*). The importance of accurately determining the direction of prayer to Mecca (*qibla*) and the times or prayer created maps which were centered on Mecca, the most significant being two brass seventeenth-century (Safavid) dials which use a cartographic grid of latitude and longitude to enable their user to determine the distance to Mecca from anywhere in the then Muslim world. This aspect of geographical thinking is still practiced in the Muslim world today.

Self-Identification

Science

In Islam, the geographical tradition did not develop into a distinct science in its own right so as to be formally taught as such in the Islamic educational system. It remained a loose conglomeration of systems of knowledge, some of which were discrete but most of which overlapped. Thus, al-Biruni (d. ca. 1050) combined descriptive geography with geodesy and astronomy, while Ewliya' Celebi compiled a ten-volume travel account compiled over some 40 years (1631–1670) of travel through the Ottoman lands, in the employ of ambassadors and governors or with the armies, and the maker of one of the Safavid *qibla*-disks seems to have learned his mathematics from his father.

Relevance to Science and Religion

The distinction between “science” and “religion” would not have presented itself to those working in the Muslim geographical tradition, for whom all science was essentially a response to God’s gift of creation and to the Qur’anic injunction to study creation. This led on occasion to the composition of books of *mirabilia*, marvels of creation.

Sources of Authority

The most important source of authority is the Qur’an, the word of God as revealed to man by His messenger Muhammad. The Qur’an sketches a basic geography of sacred and non-sacred space and a cosmology of seven heavens, and equal number of layers of earth, with earth being surrounded and covered by two oceans, which informed all geographical thinking in Islam. Translations of the works of Ptolemy and Marinus provided thinkers with the terrestrial division into climes (though this was not the only division they employed: they also used the Persian division into seven, equal, concentric circles). Central to astronomy were the Indian computational tables translated from Sanskrit.

Relevant Themes

For many moderns, any form of “religion” necessarily delimits any form of “science.” The tradition of geography in Islam allows us the opportunity to study a discipline in which scientific accuracy and discovery remained consistent with the belief system of Islam while also constituting a reaction to how the system interpreted its sacred scripture.

[Mensuration](#)

Description

Mensuration in any premodern culture was a fundamental part of the training of surveyors, architects, and other professionals. By representing lines, areas, and bodies by their numerical measures, geometrical problem solving becomes a part of calculation, or *ḥisāb* in the Arabic tradition. We first encounter practical geometry in a chapter of al-Khwārizmī's *Algebra* (early ninth century) and in later texts it appears both in stand-alone treatises as well as in chapters in books on calculation. One example of the latter is al-Karājī's seminal *Sufficient [Book] on Calculating* (early eleventh century). These books provide the basic rules of calculating sides, areas, and volumes, utilizing quadratic methods like the Pythagorean theorem as well as approximations.

Most practical books are devoid of proof, but by the latter tenth century the Greek tradition is found integrated into some texts. In his important *Book on What is Necessary from Geometric Construction for the Artisan* (ca. 990) Abū al-Wafā' relies on Euclidean geometry as a foundation for the techniques useful in the trades. One notable application of geometry to architecture is the construction of domes in Islamic architecture.

Geometers working in the scientific direction adopted the philosophical and logical framework of Greek geometry. The first translation of Euclid's *Elements* was made sometime before 805. This was followed by translations of the more advanced works of Archimedes, Apollonius, Theodosius, Menelaus, and others. The Banū Mūsā (ninth century) in particular were eager to read and understand Apollonius' *Conics*. They could not make sense of their corrupt copy of the Greek text, so al-Ḥasan ibn Mūsā derived the basics of the theory of conic sections on his own. After his death his brother Aḥmad traveled to Syria, where he found Eutocius' commentary on the first four books. From this he was able to understand Apollonius' treatise, which allowed him to supervise the translation of all seven extant books.

Inspired by Archimedes' *Measurement of the Circle* (tr. Thābit ibn Qurra) and *On the Sphere and Cylinder* (tr. Ishāq ibn Ḥunayn, revised by Thābit), the Banū Mūsā and others in their circle found areas and volumes of curved regions and solids. The Banū Mūsā derived formulae differently from Archimedes, by expressing their results as products of given magnitudes. Thābit, in his *Book on the Measurement of the Conic Section called Parabola*, proved Archimedes' formula for the area of a segment of a parabola, and he gave the volumes of several regions obtained by rotating such segments around particular lines. These proofs were later improved by Ibrāhīm ibn Sīnān, al-Kūhī, and Ibn al-Haytham (Rosenfeld and Youschkevitch 1996).

This high level of work with conic sections was continued in the tenth century by geometers including al-Sijzī and al-Qūhī. One of al-Qūhī's more remarkable results was to "construct a spherical segment whose [spherical] surface is equal to that of one segment and whose volume is equal to that of another" (Berggren 1996, 140). He also wrote a treatise on the "perfect compass," an instrument he designed for drawing conic sections. Other problems, such as trisecting the angle and constructing the regular heptagon, were solved using conic sections.

Ibn al-Haytham (965-ca. 1041, known as Alhazen in the Latin west) is best known for his work in optics, but he also made significant contributions to geometry and astronomy. His most famous result in geometry is his solution to "Alhazen's problem": given a reflective surface (which can be planar, spherical, cylindrical, or conical) and two points off the surface, to find the point(s) on the surface such that light shined from one of the two points will reflect to the other. The six lemmas which form the foundation for his solution exhibit a mastery of conic sections. Ibn al-Haytham also wrote *Completion of the Conics*, his reconstruction of the lost eight book of Apollonius' treatise (al-Haytham 1985).

Various criticisms of the foundations of Euclidean geometry were challenged by Arabic geometers. One important debate concerned

Euclid's parallel postulate. Briefly, Greek postulates were ideally simple, self-evident truths which require no proof. But the fifth postulate in the *Elements* reads like a proposition: "That, if a straight line falling on two straight lines make the interior angles on the same side less than two right angles, the two straight lines, if produced indefinitely, meet on that side on which are the angles less than the two right angles" (Euclid 1956, 202). It was only in the early nineteenth century that mathematicians showed that this postulate is in fact independent of the others, and cannot be proven.

Criticism of the parallel postulate began in ancient Greece, and continued in the Islamic world. Three approaches were taken to address the problem: Some geometers tried to prove it outright, others redefined the word "parallel," while still others came up with a more intuitively appealing alternative (Jaouiche 1986).

Euclid defined two lines to be parallel if, when produced indefinitely, do not meet in either direction. Thābit ibn Qurra and Ibn al-Haytham both substituted Euclid's definition with one which defines two lines to be parallel if they are equidistant, and from this they were able to prove the fifth postulate. But in their proofs both mathematicians generated a second line parallel to a given line by the motion of a point. Euclid, following Aristotle, had banned motion from geometry, and on this ground al-Khayyām rejected Ibn al-Haytham's solution.

In another proof Ibn al-Haytham proposed a postulate to replace Euclid's fifth: that two intersecting lines cannot both be parallel to a third line. This became known as Playfair's postulate when it was reinvented by European mathematicians. Al-Khayyām also replaced Euclid's postulate by one equivalent, which asserts that two converging lines must intersect.

Arabic geometers also criticized and reworked Euclid's definition of proportional magnitudes (Book V, def. 5), rearranged the definitions and the propositions in Book I, and composed new books 14 and 15 to be appended to Euclid's treatise.

The roles of analysis and synthesis in proofs, and even the definition of the former, were

discussed briefly by a few Greek mathematicians (Pappus in particular). Arabic authors devoted considerably more attention to the problems. The first treatise devoted to this topic in any language is Ibrāhīm ibn Sinān's tenth century *Treatise on the Method of Analysis and Synthesis* (Bellosta 1991).

Beginning with al-Khwārizmī, we frequently find geometric problems solved numerically by algebra. For example, Abū Kāmil's *On the Pentagon and Decagon* (latter ninth century) gives algebraic solutions by naming an unknown line "thing" and setting up and solving a quadratic equation. Also in the ninth century al-Māhānī used algebra to analyze a problem of Archimedes which yielded a cubic equation. This led ultimately to al-Khayyām's geometric treatment of algebra (See the entry "► [Algebra in Islam](#)").

Most geometers were also astronomers. Ptolemy's geometric models were adopted and adjusted, plane and spherical trigonometry were developed from both Greek and Indian ideas, and the construction of instruments relied on stereographic projection (astrolabes) and conic sections (sundials) (See the entries "► [Astronomy in Islam](#)" and "► [Mathematics in Islam General](#)").

Geriatrics

Herbert F. Durwen
Klinik für Akut-Geriatrie,
St. Martinus-Krankenhaus, Düsseldorf, Germany

Description

According to the definitions of the EUGMS (European Union Geriatric Medicine Society), geriatrics is the medical discipline that is particularly concerned with physical, mental, functional, and social aspects of disease as well as its acute, chronic, rehabilitative, or preventive treatment and care in patients with old or older age, including the end of life period. These patients are characterized by their high degree of frailty and multimorbidity needing a holistic approach of treatment. The presentation of disease in elderly patients can be different from that in younger age because of changing physiology with older age. Therefore, diseases in the elderly can be difficult to diagnose and sometimes difficult to treat properly. In addition, it often demands for social support measures. Geriatric medicine follows the principles of the international classification of impairments, disabilities, and handicaps and provides additional treatment offers in a multidisciplinary team setting. The main goal of geriatric medicine is to promote health by preventing and treating diseases and disabilities in older adults. It attempts to optimize the functional status in elderly patients, to improve their quality of life as well as their autonomy. Geriatric medicine is not specifically

defined by age, but primarily deals with the typical multimorbidity in elderly patients. Most patients in geriatrics are beyond 65 years of age; however, the typical geriatric conditions of disease mostly develop in the age range of the eighties and even beyond.

There is a broad range of diseases associated with older age, particularly stroke, heart disease and syncopes, infections, diabetes, mobility disorders like parkinsonism, as well as delirium and dementias. With the sociodemographic development and longevity, the importance of neurogeriatric diseases is becoming more and more obvious. However, geriatric medicine not only focuses on particular diseases but also on complex functional syndromes like immobility, instability, incontinence, and impaired intellect.

The term “geriatrics” was proposed for the first time in 1909 by Dr. Ignatz L. Nascher from Vienna, the “father” of modern geriatrics, who later on became the Chief of Clinic in the Mount Sinai Hospital Outpatient Department in New York. In 1914, he wrote the first modern geriatric textbook with the title “*The diseases of old age and their treatment*.” In the United Kingdom, modern geriatrics started with Dr. Marjorie Warren, the “mother” of geriatrics who emphasized that also rehabilitation was essential to the care of older people. In Germany, Geriatrics was promoted by the internist Max Buerger who founded the “German Society for Geriatric Research” in 1938 in Leipzig. However, it lasted over 30 years, until the first chair for geriatric medicine in Germany was established at the University of Erlangen-Nürnberg.

Thus, in Germany, geriatric medicine started to be established only after World War II. The development of Geriatrics, however, was different in different European countries, including the modalities and forms of organization of geriatric medicine. In some countries, geriatric medicine became a discipline by its own, whereas in other countries, it is still a subdiscipline of internal medicine, even if geriatric medicine asks for a multidisciplinary approach and competence.

Today, in most countries, geriatric care is represented on the level of community hospitals, whereas the representation of geriatrics on

an university level is not the same in every country. In most countries, geriatrics at an university level still has to be developed further. In recent years, research in geriatrics has primarily focused on care. Furthermore, in several countries, special centers for age research have been founded, integrating clinical geriatrics, but primarily being devoted to molecular biology.

In the future, the importance of geriatrics will increase continually as the population ages and the aging population lives longer.

Self-Identification

Science

Geriatrics is related to the science of Gerontology, which is the study of the aging process in all its aspects, social as well as biologic. Thus, it is the medical branch of health care dealing with the problems of aging and particularly with the diseases of the aged and has its origin from internal medicine. According to these roots, geriatrics has always self-identified, from the very beginning, as an integral part of natural science. Even if geriatrics primarily focuses on care research and has certain religious as well as philosophical implications at the end of life period, it sees itself as a scientific endeavor with the aim to enhance the knowledge about the organization and function of the human body in older age as well as their disease-related abnormalities. This also means that geriatrics knows to integrate scientific evidences from neighboring disciplines into its own concepts of multidisciplinary approach, diagnosis, and treatment of diseases in the elderly. These evidences are derived from traditional scientific methods of the natural sciences for clinical and basic research, applied in the classical medical subdisciplines of anatomy, pathology, pathophysiology, and physiology. In general, the disease concepts and practices of clinical investigation were developed in the twentieth century and continuously substantiated by clinical research. Over the recent decades, the methodological repertoire was extended to chemistry, immunology, radiology, pharmacology, and molecular biology. Thus, the medical

concepts in geriatrics are based on insights from a broad range of science specialties in basic research fields.

However, particular research fields in geriatrics focus on health care as well as on specific conditions. An important issue in clinical geriatric research is the treatment and prevention of "delirium," the investigation of the different aspects of frailty as well as the fact of different pharmacological constitutions with older age. Further important topics are mobility and the risk of falls in older age as well as the management of cognitive disturbances and other neurogeriatric issues.

The scientific basis of geriatrics is reflected by different national as well as European scientific societies, which run their regular scientific meetings and in the majority have their own scientific journals. These societies show an increasing number of members over the recent years.

Religion

There are close relationships of geriatrics to ethical and/or religious questions, particularly in very old age and in the end of life period.

Elderly persons often cannot make decisions for themselves. Therefore, they need people around them, who take care for them in a very responsible way. In this context, the geriatrician plays an important role providing guidance for the patients as well as for their relatives in a situation where they do not understand what happens to them or do not have the competence to understand the facts and make the right decisions. Furthermore, it is very well known that for most of the elderly, religion plays an important role in their life. In addition, there is evidence that religion correlates with improved physical and mental health. If religion by itself is helpful or if concomitant psychological benefits and social support or encouragement of healthful practices may be relevant is not yet clear until today.

In any case, the geriatrician ought to support the patient and his relatives in the best interest of the patient according to medical guidelines, but also to legal, social, ethical, or religious aspects. Particularly, in the end of life period, social, remedial, palliative, ethical, or religious issues

are becoming more and more important. Therefore, in this specific period of life, geriatrics tries very much to integrate the personal ethical or religious views of a patient into the medical treatment concept. This means indeed that geriatrics is more often influenced by ethical and religious questions than any other medical discipline.

Characteristics

Geriatrics differs from standard adult medicine and the other medical disciplines because it focuses on the particular and complex needs of the patients in older age and emphasizes maintaining functional independence. However, the presentations of illness in old age are often nonspecific, because the aged body is different physiologically from the younger adult body, and the clinical characteristics of diseases are contaminated by the decline of various organ systems with age. This means, that older persons react to illness and diseases differently than younger adults. Furthermore, previous health issues and lifestyle choices produce a different constellation of diseases and symptoms in different people. In addition, functional abilities, independence, and quality of life issues are of great concern to geriatricians and their patients. Therefore and different from other medical disciplines, geriatrics focuses not only on single disease entities but also on functional syndromes, mostly caused by several different diseases. The major categories of these impairments in the elderly are immobility, instability, incontinence, and impaired memory. They are also known as the “four geriatric giants.” Furthermore, geriatrics takes care of not only acute illnesses in later age but also of chronic diseases, as well as health promotion and disease prevention in later life.

Different from other medical disciplines, geriatrics chooses a holistic approach to medical questions in the elderly and therefore is simultaneously concerned with clinical, preventive, remedial, palliative, social, and ethical or religious aspects of illness in old age. The various challenges of frailty, complex comorbidity, different patterns of disease presentation, slower

response to treatment, and requirements for social and spiritual support call for special medical skills.

A geriatrician should have profound knowledge in the wide range of diseases in older age and their social implications as well as specific skills to treat older patients with sensitivity and dignity. Furthermore, the complex aspects of geriatric medicine require a comprehensive assessment of illness and disability and therefore an interdisciplinary approach, meaning that the geriatrician will work with other physicians, nurses, social workers, dieticians, physical therapists, occupational therapists, and other health professionals as well as family members, in order to provide comprehensive care for these patients with multiple needs. Thus, geriatric medicine is by its very nature a discipline that is multidisciplinary, community oriented, and particularly family centered.

According to its holistic views, geriatric medicine is not only interested in the treatment of acute or chronic diseases by pharmacological or interventional approaches but also in the patients’ physical and cognitive training as well as their psychological and social well-being. Furthermore, the primary or secondary prevention of disease is also an important issue in geriatrics, focusing on suitable exercise, rest, adequate nutrition, and maintenance of proper body weight. In addition, regular and thorough medical examinations are another essential factor in the control of illness in older age.

Thus, geriatrics includes medical, rehabilitative, preventive, social, and ethical or religious aspects.

Relevance to Science and Religion

Geriatrics understands itself as natural science; however, there are many ethical or religious implications, particularly concerning with loss of autonomy, aspects of beneficence, and non-maleficence, as well as justice. Particularly in geriatrics, questions like decisional capacity and competence, identification of decision makers, decisions about long-term care, resolution of

conflicts about care, or the termination of treatment at the end of life are of special ethical importance. Furthermore, aging by itself as well as the end of life period with questions like quality of life, palliative care, euthanasia, death, and dying, as well as beliefs in postmortem life are highly relevant in geriatric medicine.

Thus, more than any other medical discipline, geriatrics is involved in ethical, religious, philosophical, psychological, and social questions. Therefore, the geriatrician should be prepared to answer his patients' questions of this kind and to integrate their views and those of their families into his medical treatment strategies. Furthermore, the geriatrician must have high ethical or religious standards, because the elderly, more than patients of younger age, are often physically or psychologically dependent and require professional guidance or assistance for the management of their personal needs in their own best interest.

Sources of Authority

The authorities in geriatrics are those scientifically interested physicians who are also instrumental for the establishment of dedicated clinical as well as academic institutions. The first modern geriatric hospital was founded in Belgrade, Serbia, in 1881 by Dr. Laza Lazarevic, whereas the term "geriatrics" was coined for the first time by Dr. Ignatz Leo Nascher in 1909 who edited the first textbook in geriatrics in 1914. He is considered to be the father of modern geriatrics. Later, he became Chief of Clinic in the Mount Sinai Hospital Outpatient Department in New York. Other important geriatricians are Max Buerger, who founded the German Society for Geriatric Research in 1938, Dr. Marjorie Warren, who emphasized on rehabilitation in older patients, and Dr. Bernard Isaacs, who described for the first time the syndrome character of geriatrics with the so-called four geriatric giants (immobility, instability, incontinence, and impaired intellect).

With the advent of the internet, electronic publishing, and electronic libraries, original publications in scientific journals have become

increasingly important. Based on this rapidly growing body of knowledge, the geriatric scientific organizations have established guidelines for good clinical practice and evidence-based guidelines, often together with the scientific organizations of the neighboring disciplines. They are constantly updated for therapeutic protocols of the major geriatric disease entities.

Ethical Principles

As for every medical subdiscipline, geriatrics is guided by the oath and law of the ancient Greek physician Hippocrates, who is considered to be the father of medicine. The oath is considered all over the world to be the rite of passage for all practitioners of medicine. This Hippocratic Oath has been supplemented by the Declaration of Geneva in 1948 and later on by the rules of the Declaration of Helsinki. Thus, the basic ethical principles, which also guide the discipline of geriatrics, are autonomy, beneficence, non-maleficence, and justice.

Key Values

The key values in geriatrics are the same as in other medical subdisciplines. The primary intention of geriatric activities is to alleviate human sufferings in older age, resulting from acute and/or chronic diseases as well as from end of life problems and even death. These sufferings usually result from different diseases (multimorbidity) and implicate multiple functional impairments of different kind. Therefore, the geriatric approach is multidisciplinary and includes medical, rehabilitative, preventive, palliative, and social aspects. Usually the geriatrician employs and seeks to refine science-based therapies that are able to alleviate or even cure the underlying diseases and syndromes. Furthermore, geriatrics is very much involved in the counseling and guidance of patients and their relatives during and after acute disease as well as during the course of chronic impairments. Particular responsibilities are requested in

patients with physical and mental handicaps, personal dependence, and with very individual aspects in the end of life period.

Gifford Lectures

Neil Spurway

University of Glasgow, Glasgow, Scotland, UK

This series of lectures, unquestionably the world's most highly regarded in their field, was initiated in 1888 under the bequest of Adam, Lord Gifford, a judge of Scotland's Court of Session, who had died the previous year. The bequest was distributed (not quite evenly) between the four Scottish universities of the time: Aberdeen, Edinburgh, Glasgow and St Andrews, and the academic governing bodies (Senates) of the four universities have operated their own series of Gifford Lectures independently and usually biennially ever since, except during the Second World War. Thus, to represent a volume as "The Gifford Lectures for" a particular year is never correct: one should always add "in the University of. . ."

The Will

Lord Gifford defined natural theology in the widest terms: "The Knowledge of God, the Infinite, the All, the First and Only Cause . . . and the Knowledge of . . . the Relations which men and

the whole universe bear to Him, the Knowledge of the Nature and Foundations of Ethics or Morals, and of the Obligations and Duties thence arising.” Even wider, and strikingly liberal, was the specification as to who might be invited to take up this challenge: “The Lecturers appointed . . . shall not be required to . . . subscribe any declaration of belief . . . they may be of any religion or way of thinking, or . . . of no religion . . . provided only that they be able and reverent men, true thinkers . . . and earnest enquirers after truth,” for “nothing but good can result from free discussion.” Nevertheless, there was a constraint: “I wish the lecturers to treat their subject as a strictly natural science, the greatest of all possible sciences, . . . that of Infinite Being, without reference to or reliance upon any supposed special exceptional or so-called miraculous revelation.” Tall order though this was, he finally required that the lectures be “public and popular . . . open not only to students of the Universities, but to the whole community without matriculation.”

Early Lecturers

The first series of Gifford Lectures was given in Edinburgh by a freelance philosophical writer, James Hutchison Stirling. He was a popularizer, and his lectures met the last of Lord Gifford’s conditions better than almost any since – probably only Carl Sagan (Glasgow 1985), who filled three lecture theaters by video link, matched him in this respect, and regrettably Sagan’s lectures were never published. Of the opening group of lecturers, however, the great philologist and Vedic scholar, Max Müller (Glasgow, 1888–1892), German by birth and training but by then an eminent Oxford professor, made the most lasting mark with his 4-volume series on *Natural Religion* (the first volume’s title). Much the same theme recurred frequently till 1911–1913 (Sir James Frazer, St Andrews), after which Senates (or their lecturers) faced up to the difference between natural religion and natural theology, and adhered more consistently to Lord Gifford’s intention. Nevertheless, one of the greatest series ever, by the American William

James (Edinburgh, 1900–1902), on *The Varieties of Religious Experience*, had broadly such subject matter; James, however, built upon it an edifice of psychological and philosophical insight unmatched by any other lecturer of the period.

The other main groups of early lecturers were philosophers, more or less heavily influenced by Hegel. Edinburgh’s second lecturer, however, was the physicist Sir George Stokes, a latter-day Paley, who elegantly restated the argument from design (1890–1892). This certainly was natural theology, but it was to be the next century before another scientist was invited.

Scientists in the Twentieth Century

The German biologist Hans Driesch, the last great exponent of vitalism, opened this account (Aberdeen, 1907–1909). The next biologist was Lloyd Morgan, presenting a philosophy of evolution and emergent mind in St Andrews (1921–1922). The greatest biological lectures, however, were surely those of Sir Charles Sherrington, whose *Man on His Nature* (Edinburgh, 1937–1938) was a towering account of mind and brain, and their interactions with the environment, as understood at the time. Later biologically trained lecturers included an Anglican churchman, Charles Raven (Edinburgh, 1950–1952), with an admirable overview of science and religion, and Sir Alister Hardy (Aberdeen, 1963–1965) who was researching religious mysticism as objectively as he had previously researched marine organisms. In Edinburgh again, the Australian neuroscientist, Sir John Eccles (1977–1979), was more dualist (and therefore anachronistic?) than his teacher Sherrington. Far better neurophilosophy was presented by Donald Mackay (Glasgow 1985–1986), whose memorable *Behind the Eye* presents “I-story” and “brain-story” as accounts of the same system from opposite sides. Equally notable, as the century neared its close, was the biochemist-theologian Arthur Peacocke (St Andrews, 1992–1992), whose lectures became part of an enlarged edition of *Theology for a Scientific Age*.

One of the greatest physical scientists was Sir Arthur Eddington (Edinburgh, 1926–1927), whose *Nature of the Physical World* tinged quantum physics with mysticism in limpid prose. Neils Bohr (Edinburgh, 1949–1950) did not publish, but Werner Heisenberg (St Andrews, 1955–1956) did so with both lucidity and depth, while his fellow German, Carl von Weizsäcker, a Kantian and theistic cosmologist, presented perhaps an even more rounded viewpoint to his audience in Glasgow (1959–1961). The next physicist to deliver a full series was the last of the century, Sir John Polkinghorne (Edinburgh, 1992–1993) in the well-known *Science and Christian Belief*.

Philosophy and Theology

There was, as already implied, much philosophy in the great scientific series. Reciprocally, at least two mainstream philosophers drew strongly upon science. Samuel Alexander's account of a still-unfolding *Space, Time and Deity* (Glasgow, 1916–1918) provides an archetypal Gifford title! Yet more lastingly influential has been A.N. Whitehead's *Process and Reality* (Edinburgh, 1927–1928) – not an easy read, despite Lord Gifford's wishes, but the central text of process thinkers ever since. Still more extensively quoted has been the ex-scientist, Michael Polanyi's, exposition of the tacit and prerational dimensions of all *Personal Knowledge* (Aberdeen, 1951–1952). Less widely known, yet to its admirers one of the most systematic natural theologies the benefaction has ever elicited, was John Macmurray's assertion of the primacy, first of *The Self as Agent* over the self as thinker, and then of *Persons in Relation* over persons as individuals (Glasgow 1952–1954). The first woman lecturer, Hannah Arendt, considered *The Life of the Mind* in Aberdeen (1972–1974); simultaneously in Edinburgh, A.J. Ayer's *Central Questions of Philosophy* excluded the possibility of theology, but in counterpoint Richard Swinburne (Aberdeen, 1982–1984) offered a closely argued, modern-traditionalist account of *The Evolution of the Soul*.

The borderline between philosophy and theology is no firmer than that between philosophy and science – witness Alvin Plantinga's two volumes on the warrants of belief (Aberdeen, 1986–1987). Only in the 1920s did the Senates begin frequently to invite theologians to lecture, and among the most notable in the early group was the Anglican Archbishop William Temple's *Nature, Man and God*, a commanding attempt at an overall natural theology (Glasgow, 1932–1934). Even more prominent was the Swiss theologian Karl Barth's attack on the very possibility of natural theology (*The Knowledge of God and the Service of God*: Aberdeen, 1937–1938) – another volume which spurned the benefactor's last requirement yet has attained an influence inversely proportional to its accessibility. The Swedish Archbishop Nathan Söderblom (Edinburgh, 1930–1931) had been immensely more liberal, while Edwyn Bevan's *Symbolism and Belief* (Edinburgh, 1932–1934) was among the most elegant individual contributions to the series. Albert Schweitzer also lectured during this period but did not publish.

Replies to Barth came after the Second World War, the most direct being from a fellow Swiss, Emil Brunner, in the two volumes of *Christianity and Civilization* (St Andrews, 1946–1948). From the USA Paul Tillich (Aberdeen, 1952–1954) and from Germany Rudolph Bultmann (Edinburgh, 1954–1955) also stand out at this time, while a little later *The Openness of Being*, by the Anglican Thomist E.L. Mascall (Edinburgh, 1970–1971), was a notable theological edifice. In the latter part of this period, several lecturers considered non-Christian religious thought. Notable among these were R.C. Zaehner (*Concordant Discord*: St Andrews, 1967–1969), Ninian Smart (*Beyond Ideology*: Edinburgh, 1979–1980), and Seyed Nasr, the first Muslim lecturer (*Knowledge and the Sacred*: Edinburgh, 1980–1981).

Then and Now

The above account is a condensation of that by Spurway (1993). More detail, up to the mid 1990s, is provided by Jaki (1995).

The Gifford Lectures continue undiminished in all four universities. To give selective prominence to any very recent ones would be invidious, but they are listed and in most instances summarised at www.giffordlectures.org. Instead, let this article end with two quotes from Max Müller to which Lord Gifford would surely have assented:

It is truth which makes revelation, not revelation which makes truth. (*Physical Religion*, p. 361)

What is natural is divine, what is supernatural is human. (Preface to *Collected Works*, p.xv)

Description

The study of Christianity as a global religion has in recent years occupied a number of scholars in contemporary Christian systematic theology (Kim and Kim 2008; Schreiter 1997), historical studies (Stackhouse 2000; Jenkins 2002a; 2002b), as well as sociology of religion (Robertson 1992; Kurtz 1995; Beckford 2003; Beyer 1994, 2003, 2006). During the last century, Christianity has undergone a number of fundamental shifts demographically, socially, and culturally: whereas a typical Christian in the year 1908 was a white, European, literate, middle-class man from an industrial city, the typical Christian in year 2008 is a colored, African, illiterate, poor woman from a village in Nigeria. In this situation, the main scholarly question has been what kind of changes Christianity's globalization brings about – that is, by its changing geographical, cultural, and social parameters – and how these changes affect the very nature and theology of Christianity itself. This is a complex question and has been discussed mainly within three major theoretical concepts, namely, “globalization,” “postcolonial theory,” and “pluralism.”

Fundamental Shifts Accompanying the Globalization of Christianity

The transformation within Christianity during the last century has resulted in its globalization and caused a fundamental shift in two areas.

First, even if the historical spread of Christianity has been eastward and southward as well as westward, Christianity was to a large degree a European and subsequently American religion until the start of the twentieth century. In the course of the last century, Christianity has gained a new presence across the globe in countless local expressions which are linked by crisscrossing networks. Christianity outside of Europe and North America is not uniform or united but is made up by a number of Christianities, ranging from Orthodox churches over Roman Catholic and various Protestant churches to a plurality of Pentecostal and charismatic churches. At present, there are many global networks bringing churches and leaders together, but the prospect of a single world Christianity seems very remote. Global Christianity is in fact a plurality of Christianities.

Second, while European and to a lesser degree American Christianity has been declining in the last century, there has been a marked growth in Christianity, especially in sub-Saharan Africa and in Asia. This simultaneous decline in European Christianity and growth in African and Asian Christianity has caused a historical shift which means that there are now more Christians living outside of Europe and North America than within these regions. Consequently, the strength of Christianity now lies outside the old strongholds of Christendom. Outside of Europe and North America, Christianity has been spread by Roman Catholic missions since the sixteenth century and by Protestant missions since the eighteenth century. However, the present spread of Christianity is primarily caused by local believers and in forms developed by them in local ways; thus, Christianity's globalization has also meant its indigenization. Attention to the activities of foreign missionaries has tended to obscure this fact, but the present diversity of global Christianity is a testimony of it.

Statistics on the Globalization of Christianity

Statistics confirm these two fundamental shifts: The total number of Christians of all

denominations in year 1900 was approximately 560 million or 33% of the world's population. Within the last 30 years, developments in Africa and Asia show a dramatic increase in numbers of Christians. African Christians were 63 million in 1970, but in 1995 they numbered 151 million (Barret et al. 2001, p. 4). If the same rate of growth is projected to 2025, the total number of Christians in Africa will then be 600 million. This would in other words be a tenfold increase in the number of Christians in Africa in merely 55 years. Also in Asia does Christianity show high growth: from 52 million in 1975 to 148 million in 1995. Projected to 2025, this growth would mean an increase to 460 million. Again, this would be a tenfold increase in the numbers of believers (Barret et al. 2001, p. 4). Turning back to Europe, the number of Christians is by large unchanged: from 326 million in 1975 to 370 million in 1995, but the percentage of Christians has clearly gone down in Europe over the last 60 years from more than 75 % self-declared Christians in Western European countries to merely 40 %. However, because of general growth in population during the same period of time, this means that the total number of Christians has remained somewhat stable, around 32–34 % of the world's population.

Themes Arising in Globalized Christianity

The expansion of Christianity has brought up different themes in various social and cultural settings. Whereas the historical European Christianity has emphasized certain themes, new points have emerged according to the spread of Christianity. Even if it is impossible to give a comprehensive overview of these themes in a single entry, a few keywords and regional concerns might be mentioned.

Historically, European Christianity has mainly been made up by Roman Catholicism and various Protestant forms of Christianity and only to a lesser degree by the presence of Orthodox Christianity. Each of these forms of Christianity emphasizes their own aspect of the

Christian tradition: While Orthodox forms theologically emphasize the Trinitarian theology and the fundamental unity of faith, Roman Catholic forms focus on Jesus as Christ and the Church as his body and bride, and Protestant forms on the contemporary significance of the Bible for society and life.

Somewhat in contrast to these focal points, African Christianity seems to have been especially concerned with the relationship between indigenous African traditions and Christian religion, and especially the large revivals in East and Central Africa has brought out the question of the relationship between ancestors and Christ. All over Africa, a large number of independent African churches have arisen, the so-called AICs, African independent churches. These are interesting especially in the light of globalization because they in their practice and theology formulate a conscious alternative to European forms of Christianity. Recently, the experiences of apartheid and reconciliation in South Africa have given rise to new forms of indigenous theologies, especially focusing on reconciliation.

North American Christianity has always been popular and multiple. In the twentieth century, especially the Evangelical consensus, the influence from black churches on spirituality and entrepreneurial forms of church life has formed a large part of popular Christianity, resulting in fundamentalism on the one hand and the Social Gospel movement on the other. Furthermore and of utmost importance is the emergence of Pentecostalism on the West Coast of America in the very start of the century, a form of Christianity which now has a global following of more than 350 million peoples (Barret et al. 2001).

The spread of Pentecostalism in Latin American Christianity has shifted the church demographics from a large Roman Catholic majority and a small Protestant minority to a more complex picture. Whereas Spanish-Portuguese Catholicism and indigenous forms of religions have coexisted since the Christianization of the Americas in the sixteenth century, the Pentecostal and charismatic forms of Christianity have caused a new awareness of the mix between cultural and religious elements in Latin American Catholic Christianity. A second

major impulse in and from the Latin American Christianity has been in political forms of theology, most notably in the so-called liberation theology and in its formation of base communities, opposing the alliance between conservative military dictatorships and the Roman Catholic Church and calling for political as well as spiritual liberation.

In Asia, Christianity has long been present and one might distinguish between a Nestorian, Syrian, Catholic, and Protestant period in Asian Christianity. The diversity and struggle in South Asia between ethnic and religious groups has also involved Christianity. Especially in the Indian subcontinent has Christianity been used also politically by so-called dalits (outcasts) who through mass conversions from Hinduism try to overcome what they experience as the oppressive features of caste society. More than any other single Christian group, the churches emerging from this type of Christianity have put poverty as a theme on the agenda. In China, Christianity finds itself between Cultural Revolution and neoliberal capitalism, and the developments there seems to bring out new relations between Asian cultures and the Christian Gospel, and therefore, Chinese Christianity seems destined to become a dominant form in the future.

The Middle East needs special mentioning because it is an exception in the history of Christianity as a global religion in the twentieth century. The Muslim countries in the Middle East are the major exception because although Christianity was born in this region, its globalization has not brought about significant number of conversions to Christianity. For centuries, Christians lived as a minority under the protection of Islamic rulers, but during the last century, these minorities have experienced increasing discrimination along with the resurgence of militant Islam. The future of Christianity in the region is uncertain, and the number of Christians is decreasing each year mostly because of emigration.

The variety of themes arising in the globalization of Christianity shows that Christianity is not a monolithic extension of a single Western form of Christianity but that it is a plurality of forms which each has their own political, economical, and cultural agendas. What is common in all

these forms of Christianity is only their commitment to Jesus as Christ.

Interpretation of Christianity's Globalization

The globalization of Christianity as witnessed in statistics and themes arising in global Christianity has been interpreted according to three different approaches, each tied up with one of the three theoretical frameworks mentioned initially, namely, "globalization," "postcolonial theory," and "pluralism."

First, a number of scholars have interpreted the globalization of Christianity according to theories of globalization. At a minimum, "globalization" describes the awareness of interconnectedness and interaction between peoples and societies and the simultaneous perception of the world as a whole (Robertson 1992, pp. 8–18; Beckford 2003, pp. 118–119). It has been argued that in the case of Christianity, globalization theory is especially appropriate because Christians consciously have been trying to globalize Christianity as part of their mission strategy (Beyer 2003, 2006). Therefore, through application of globalization theory, a deeper understanding of the changes which accompany globalization of Christianity might be reached.

However, a deeper understanding depends upon the model of globalization applied to the data, and here, one must distinguish between three basic types of models: (a) the core-periphery models, (b) the multiple-center models, and (c) the system-theoretical models (cf. Beyer 1994). The core-periphery models focus on dependence, exploitation, and hegemony between the periphery and core in the process of globalization. According to this model, the relation between the core and the periphery is fundamentally unjust and consists in economic or material exploitation and mental colonization. Applied on the globalization of Christianity, this model would lead to a critique of the mental colonization and hegemony involved in conversion to Christianity. The multiple-center models focus on the interrelatedness and particularization of universals. According to this model,

the tension is not between core and periphery but rather between traditional and modern forms of social organization ("community" versus "society"). This model does not focus so much on economical or material conditions as upon symbolic forms and cultural processes such as modernization. According to this model, the globalization of Christianity is facilitated by a shift from community forms to society forms of social organization, and conversion to Christianity might be viewed as part of a continuity of modernization on a global level. The system-theoretical model views global society as a large number of social systems related to each other. Each system develops independently and refers to itself through special "codes," which in Christianity's case is the binary code "immanence/transcendence." Even if any social system develops independently, any system is in constant interaction with other (equally closed) systems. From this somewhat complex viewpoint, the global society is the system which encompasses all communication between systems. The contribution from this model toward an understanding of Christianity as a globalized religion consists mainly in reminding us about the complexity of the task of understanding any system.

Second, many scholars – mainly from the global North – refer to postcolonial theory in order to explain Christianity's globalization. On a basic level, "postcolonial theory" refers to the analysis of the predicaments involved in formation of identities in postcolonial societies. These scholars point out factors such as economic poverty, disempowerment, or crises of modernity as main motivations for conversion to Christianity and the consequent globalization of Christianity as a religion (e.g., Asad 1993; Veer 1996). Although this approach seldom simply leads to a materialistic critique of religion, it is often accompanied by a core-periphery model of globalization, leading to a critique of Christianity in its globalization as an expression of spiritual colonization.

Third and somewhat related to both globalization theory approaches as well as to postcolonial theory, a number of scholars – many from the

global South – have pointed about the pluralism as the most appropriate theoretical framework for interpretation of the effect of Christianity’s globalization (Schreiter 1997; Hedlund 2000; Bevans and Schroeder 2003). In this connection, “pluralism” contrasts certain aspects of identity, most clearly to the continuity aspect of identity. Even if pluralism often seems to remain a rather abstract concept, it seems to imply the notion that the cultural, moral, and religious conditions in the global era are best described as “pluralistic.” Without denying that material conditions have effect on spiritual experiences and conversion, scholars arguing for this approach point out that as the earlier universalism of Christian theology has been replaced by a plurality of Christianities and theologies, the nature of Christianity itself must be plural and contextual, determined within particular historical, social, and cultural contexts. This approach often goes together with the second type of globalization models mentioned above, the multiple-center model.

From my point of view, the second type of globalization models – the multiple-center model – is better suited for analyzing the globalization of Christianity for three reasons: (a) because Christianity seems to be more than social and cultural epiphenomenon of material conditions, (b) because global Christianity does not have a core and a periphery in the economic or material sense of the word, and (c) because viewing the globalization of Christianity in terms of cultural processes such as modernization makes more sense than in terms of economic dependency, political oppression, deprivation, or development. Furthermore, this third type of globalization theory – the pluralism type – goes well together with the multiple-center model, which emphasizes the contextual particularization of globally accessible ideals, something which might help express the relative success of Christianity as a global religion in the twentieth century.

Effect of Globalization on Christianity

A much debated question is how exactly globalization affects Christianity and what the full

consequences of globalization are for Christianity (Robertson 1993; Beyer 1994; Riis 1999; Luke 1999). A central feature of this discussion is whether globalization of Christianity increases or decreases the homogeneity and plurality of Christianity. According to the most recent contributions in this discussion, the answer seems to be somewhat counterintuitive: globalization causes a “globalization” of religion, it is argued, in the sense that in globalization both universalization of particulars and particularization of universals take place (Robertson 2000). According to this interpretation of globalization, the globalization of Christianity might be seen as implying an understanding of Christianity as a universally accessible form particularized in various geographical, social, and cultural settings. Each manifestation of Christianity alters it a little bit and over the course of time; Christianity’s nature and theology is itself changed through its globalization.

Effects of Christianity’s Globalization on Christian Self-understanding

On the basis of this condensed presentation, there seem to be three interrelated effects of Christianity’s globalization on Christian self-understanding.

First, there is a clear change from Eurocentric to a polycentric self-understanding. If one view utilizes the multiple-center perspective on Christianity’s globalization, the Eurocentric attempts to understand what real Christianity is have to give away to a polycentric view on present Christianities in its variety of forms and emphases.

Second, according to Christianity’s globalization, there is a significant change in sociopolitical relationship. The European models of historical interrelatedness between churches and states have to give away to new forms of relationship. If modern and traditional forms of social organization clash with each other in modernizing states, Christianity might serve new functions in bringing about new relations between individuals, just as modernity brought about new relations between states, religions, collectives, and individuals.

Third, and on the most fundamental level, globalization of Christianity changes Christian identity. The changing center of Christianity and the changing sociopolitical relationship pose a question of identity for global Christianity. The question is what types of Christianities will we see in the future, and at this point, more empirical research into forms of globalized Christianity is needed.

Description

Globalization was initially a financial and economic phenomenon, and then became social, cultural, political, and philosophical. A true multidisciplinary system which, as a result of technology and the development of mass

communications (Technologies of Information and Communication, or TIC), has reshaped social relations through a model of global interdependence. All this could be verified thanks to the clearing of barriers, which has allowed, day by day, an easier and free movement of people, knowledge, information, and ideas.

Marshall McLuhan, referring to this communicative environment, defines “global village” as the world which is the size of a village easily explored, in which physical and cultural distances fall and new lifestyles are born. In such an environment new patterns of thinking; consumption and production emerge and become more uniform, converging toward a single model in the global village.

According to the semantic magnitude of the term that involves various disciplines, from economics, philosophy, geography, religion, social sciences in general, it is necessary, testing an acceptable definition, to limit the range of interest and refer to the meaning that more commonly is given to the term. For the purpose of this article, “globalization” refers primarily to the business sector and how the production and distribution of goods and finances goes beyond the borders of nation-states.

Production and distribution have to do with the interests of different sectors that pass through material goods and, so, tied to agriculture, mineral and forest resources, craft industry, and intangible assets related to education, health, public administration, justice, tourism, information, and finance. They are all linked by the possibility of trade and commerce, indeed, globally, in the sense that there is a new model of accumulation of capital mainly by the USA, Japan, and the European Union. This model tends to control the market and resources available to make a profit on a global scale and is the result of what is known as global development.

What is certain is that globalization, in the words of Gianmaria Ajani, focuses on the question of the world economy and consequently triggers other issues about the lack of a Global Governance with respect to the formation of rules, fearing also new forms of democracy and participation.

If in the past, the combination of “social consensus state-compulsion” (Ajani 2007) held for the legitimacy of the rules of law, now this legitimation is found in *functionalism*: the old procedures based on the *political utility* and, therefore, on a legitimation that, according to this principle, established its majority consensus to legitimize its action, are replaced by a functional approach, that is, the fact that the usefulness of the rule must be determined by assessment of its validity and necessity for the proper functioning of the market.

Always Ajani observes how lawmakers become guarantors of the proper functioning of their economies both to the citizens and to those organizations like the International Monetary Fund, World Bank, the European Central Bank, the World Trade Organization, which, precisely, aim the exercise of the powers’ comprehensive review on the action of regional markets.

There is in a sense, as Ulrich Beck would say, the crisis of the principle nation-state. You could say that what was for the workers of the nineteenth century the question of class, today is for companies that act at transnational level the issue of globalization with this difference, however, that while the former operated by “countervailing power”, now the global companies act, “*without a counterpower (transnational)*” (Beck 1999). It is interesting how Beck, from the analysis of the *Communist Manifesto* by Marx and Engels, shows that in fact class-based debate is more current than it seems, in particular as regards the role of the revolutionary bourgeoisie, exploitation of the world market, the similarity of the basic assumptions of the neoliberal and Marxist and, finally, the questioning of the nation-state perspective, guilty, according to the sociologist, of the trappings of the social sciences until today. Beck’s analysis stresses on this latter point, that is to say globalization is understood as a breaking of the unity between the nation-state and national society, which means, on the one hand, the creation of new competitive relationships and power “conflicts and intersections between unity and national-state actors” and the other “actors, identities, social spaces, transnational processes and conditions” (Beck 1999).

The problem is that a world society takes shape without a World State, which would mean to have no politically organized community so to create new opportunities for transnational action and power without any democratic legitimacy.

In a way it would require a synthesis, based on a “re-localization” that would not be a return to tradition, but rather a necessary synthesis between global and local. This is called “glocalization” a term borrowed from Roland Robertson and which means, at the same time, de-localization and re-localization.

This line of interpretation gives rise to the possibility of forming a transnational state with an “inclusive sovereignty,” a state, which, even if it does not set the elimination of the national state, it would be beyond it. This is achieved through a policy organized on several levels: in a position to interpret and redefine both the general and the particular, and according to a worldwide point of view, a policy of coordination of a plurality of transnational states.

A crucial role in this sense is attributed to civil society that, even before the political institutions, is already projected in a global context: the world society is not the annulment of the national societies, but in fact a new horizon, that distinguishes the global from globalization. Globalization, as a dynamic process, finally takes on the character of the reciprocity of global-regional relations, including the further report and self-defined by the mass media. They redefine the social spaces and their understanding and representation at all levels: cultural, political, financial, military, and economic.

In this way, Martell summarizing the different positions of sociologists such as Waters, Giddens, Holton, Held and historians as Osterhammel and Petersson, poses, as a condition of globalization, the understanding of space and the development of international relations.

So, if it is true that globalization should have a *global extension*, it is necessary to reflect the extent to which an economy, a policy, or a regional culture with transnational extension should be considered global. It means that maybe an exaggeration to say that, to talk about globalization, it must necessarily reach the whole

world; rather, it may suffice if it reaches all continents and most regions of those continents.

On the other hand, even Westernization realizes the inclusive action at the global level of globalization, that is, a phenomenon which exports ideas and products from one side of the world to another and that causes a real expansion of a part of it. Again, no one can pretend that all parts of the world give a contribution of equal size, but it is necessary however, Luke Martell says, that globalization, to be global, must not be a discriminatory process in any way to predict the inputs from the all continents and countries that constitute them. Another point that defines globalization is the interdependence and not only the interconnection.

This means to assess the relationships and trade between countries: to achieve interdependence, is necessary, in case of trade crisis between two countries, to assess the real consequences on workers and on the economy of the exporting and importing company. So, the reports must “create a structure or a system,” that is to have some stability and regularity. Finally, globalization must involve not only the elite but also the masses. This is because a global consciousness can only rise when people have the perception of the world as one place. However, these criteria are too strict because a phenomenon can completely fall, giving historians and skeptics of globalization the opportunity to say that today the phenomenon internationally widespread is not *real* globalization. Actually Martell asserts again, that one must consider globalization not as an aim, but as a process that comes close to these criteria in order to understand it and, especially, to say that it is really taking place. But it is even more necessary to talk about globalization because, from a sociological point of view, this notion, is able to underline aspects as power, inequality, and conflict inherent in the phenomenon itself. While the optimists argue that globalization is a positive, democratic, and profitable process that, thanks to the cultural contamination gives rise to a new form of cosmopolitanism, through which is also possible to spread positive values such as fundamental and universal rights of man, it is also true that, in

analyzing this phenomenon, there are striking themes of power, inequality, and conflict in world relations. In this sense, you can think how some actors play a greater role than others, some are more integrated than others who, sometimes, are even excluded.

Saskia Sassen, for her part, offers a perspective according to which globalization would not erase all of the nation-states, but rather change their work at best. That's because the states would emerge in a position of "strategic dominance" for the development of globalization. So, the concept of sovereignty is changing, not the state, which is structured on the relationship between global and local; in this relationship based on hierarchies, streams, links, the national state not only favors globalization, but also creates its geography composed of networks of global cities, regions specializing in the production of certain goods, interstate relations based on continental flows of capital and information through the Internet.

The question is how far a nation-state is willing to cede some of its prerogatives, especially in matters of law, so that the metamorphosis of sovereignty takes place marked by mutable exchange between the local-global and vice versa. Finally, one can't not touch the relationship between religion and globalization, in particular in their relationship, in the words of Ignazio Sanna, including planetary Company and assertion of identity. So there is a phenomenon of cosmopolitanism, a phenomenon more virtual than substantial, as it is dominated by the tyranny of finance capital, in which you witness the progressive monetization of human relationships, the banning of the subjectivity and of the person. This cosmopolitanism appeared not only in the social and cultural, but also in the more specific case of law, in which you can see a fundamental ambiguity of the concept of "universal law," where it refers to a sort of cosmopolitan legal unit that, in contrast, is not within the shared perspectives, and even, most likely, present in human desires. Sanna, then, hopes to overcome the simplifications of identity, now active in vast areas of the planet through a kind of "anthropological ecumenism," (Sanna 2011) a unification of humanity founded on religious freedom and universal brotherhood.

Obviously, in this perspective, the problem areas are those relating to the actual dialogue between religions and faiths that tend to be exclusivist, rather than inclusivist.

Gnostic

Gnosticism is a general term that has been used by many scholars over the last several centuries to typify certain belief systems and practices that were regarded by early Christianity from about 150 C.E. onward as “heterodox.” The word Gnosticism comes from the Greek word *gnosis*, which connotes a secret, privileged, and mystical form of “knowledge,” contrasting with the more conventional expression *episteme*, which refers to knowledge gained by sound, rational demonstration, and argument. It was initially used as a term of derogation by its early orthodox Christian antagonists.

At the same time, the word “Gnostic” has been employed in an extended sense by intellectual and cultural historians to identify certain common hereditary strings of thinking in Western and Middle Eastern civilizations that persist up until the present day. Gnosticism has been associated not only with libertarian, Bohemian, antinomian, and anti-authoritarian attitudes among both countercultures and certain cultural elites throughout modern history as well as with certain revolutionary and totalitarian ideologies in the nineteenth century. The work of the late political philosopher Eric Voegelin has been critical in this regard. In most of his major works, including his multi-volume *magnum opus* entitled *Order and History*, Voegelin analyzed how what he called “Gnostic” thought – the notion prevalent in Marxism, fascism, and even various “human potential” philosophies that are often well received within liberal democracy that special human insight and bold expertise can bring about a utopian transformation of human

nature and the social order. Gnosticism, finally, has been compared to the general, postwar movement known as “existentialism,” an outlook that was highly fashionable among Western intellectuals during the 1950s and 1960s and stressed the human being’s fundamental alienation as well as autonomous human striving in the face of a hostile and “absurd” universe. *The Gnostic Religion* by German-born philosopher Hans Jonas, which first appeared in 1958, compared convincingly ancient Gnostics to modern existentialists.

The study of Gnosticism is not a field or a discipline, but a general subject matter that is often a special subdiscipline of research within certain recognized fields. Since about 1980 “Gnostic” studies has burgeoned as a broad, interdisciplinary area of inquiry, mostly in the humanities. Subspecialties in the study of Gnosticism, therefore, have proliferated in a variety of fields, predominantly religious studies, Biblical studies, history of religions, and Middle Eastern and Asian studies. Because of the obvious similarity of the worldviews of classical Gnosticism and certain Oriental philosophies, a search for possible Asian links through the trading networks in the ancient world between the Levant and India and China has been one trajectory of investigation over the years. However, Gnostic studies have for the most part concentrated on a Mediterranean provenance for the general phenomenon. Since Gnosticism is almost by definition a world view rather than a self-designated community of religious believers or practitioners, and in lesser degree a philosophy of human nature and values, those academic methodologies which start from material remains are less consequential for research in this subdiscipline than those which are primarily concerned with textual artifacts and symbols.

The issue of how to identify “Gnostic” strains per se in history, thought, and culture – and increasingly whether the Gnostic “label” itself really designates anything of importance – remains an ongoing item of contestation. In his *Rethinking Gnosticism: An Argument for Dismantling a Dubious Category* (1996) Michael Allen Williams systematically takes apart what

he considered the overextension and overuse of the term in modern scholarship. He suggests that what was originally a polemical term deployed as a catch-all against a spectrum of deviants from the fledgling Christian consensus about who Jesus was and what kind of salvation he offered late morphed into a pseudo-taxonomical category. Williams makes the case that Gnosticism has become a largely useless locution to lump together countless and diverse forms of novel Hellenistic religious movements, similar to the promiscuous category of “New Age” that is routinely invoked nowadays.

Thus the study of Gnosticism, if Williams’ argument holds, is neither a field nor a subdiscipline, but a generic descriptor encompassing a wide-ranging and helter-skelter array of phenomena for something that does not really cohere conceptually, or possibly even exist in the genuine theoretical sense. Williams, who was praised for his own erudition and the precision of his line of reasoning, may represent an extreme academic reaction to debasement of the coinage of the word in recent popular culture and among those scholars who have bedded down with its enthusiasts. But he has put his figure on something that is troubling among partisans of what might be called contemporary “Gnostic studies.”

What might be called the “definitional” and “typological” difficulties with research into Gnosticism have extended even to the limited subject matter that religious historians once took for granted. Even the interrelationship between Gnosticism and what we now regard as “orthodoxy” is not as clear as was presupposed until recently. Scholarship surrounding Gnosticism took root during the nineteenth century under the influence of the new historical-critical scholarship concerning ancient Christian texts prevalent in mostly German universities. The leading researcher into ancient Gnosticism was the German historian of ideas Adolf von Harnack (2009), best known for his extensive writings on the history of church dogma. However, Harnack was limited in the scope of his research because of the lack at the time of original early sources. Harnack’s work, like most scholarships during

this period, was wholly dependent on the well-known anti-Gnostic polemics that are found throughout the writings of the early Church fathers. The standard view until very recently was that Gnosticism must be seen a foreign “gospel” that covertly insinuated its way into the early Christian congregations around the Mediterranean basin, particularly during the second and third centuries. Harnack summed up this dominant perspective by depicting Gnosticism as the “acute Hellenization” of Christianity.

More than any other scholar of the nineteenth and first half of the twentieth century Harnack was responsible for the spread of the notion Christianity was religiously unique and could be boiled down to the simple message behind Jesus’ preaching of the Kingdom of God in Galilee during the first century. Harnack was bent on showing how Christianity’s “essential” teachings were impervious to the process of syncretism, the genetic blending of different cultural ideological streams. According to Harnack, neither the “Judaizers,” whom the Book of Acts portrays as St. Paul’s chief antagonists, nor the “Hellenizers” – that is, the Gnostics, were able to corrupt Jesus’ essential message, even up until the present day. Like much of what the Germans called [▶ Religionswissenschaft](#) (the “science” of religion) throughout the nineteenth century, overwhelmingly liberal Protestant in character, Harnack was committed to the view that the new historical-critical method would ultimately not undermine Christian doctrine, but relativize and explain away all its competitors, leaving the pure “essence” of Christianity untouched. Thus early research into Gnosticism was colored strongly by a hidden agenda to preserve a certain kind of Protestant orthodoxy under the pretense of mapping out new methodologies of research in the study of religion.

This paradigm, however, was both challenged and began to shift dramatically after the end of World War II. The period between the two world wars was a kind of *interregnum* dominated, at least in Europe, by a dogmatic, albeit erudite, form of Protestant theology known as “neo-orthodoxy,” which not only did not purport to be any kind of *Wissenschaft*, or “science,” but

also held any “science” of religion as a whole largely in contempt. All sciences of religion, Barth suggested, should be dismissed exclusively as the “word of man” as opposed to the true and transformative “Word of God.” But in December 1945 some peasants living around the city of Nag Hammadi on the Nile in Upper Egypt accidentally stumbled upon a collection of ancient papyrus fragments in earthen jars that dated back to the second century of the Christian era. The papyrus documents turned out to be an actual library of original Gnostic texts, which had most likely at some time during the Constantinian era or later been squirreled away by local Christian monks, who were forbidden to possess such “heretical” writings. The so-called Nag Hammadi Library, like the even more famous Dead Sea Scrolls discovered in Palestine 3 years later, revolutionized scholarly understanding of Gnosticism and led to a revaluation of who the ancient authors of such texts actually might be. Although the texts offered little clue to their historical or social identity, they called into question the prevailing scholarly consensus and opened the way for trajectories of hypothesis and speculation that left behind the model that had been institutionalized by Harnack.

As is customary for major archeological finds, it often takes decades for new textual discoveries to bring about a significant change in the operative theories themselves. For one thing, the fragments of manuscript need to be translated, dated, and compared with other known texts. Because the Gnostic library at Nag Hammadi had been translated into Coptic from Hellenistic Greek at some point, it was not clear at first when they had actually been composed. Finally, the peasants who first found the jars with the first papyri were not aware immediately of their significance. A few years later the Egyptian government seized what was then in circulation and kept them largely from scholars outside Egypt. It was through some contraband segments of the papyri, smuggled into Europe, that interest in the manuscripts first awakened during the late 1950s.

The papyri were mostly recovered and translated into English, however, by the mid-1970s. At that point the fascination with Gnosticism

became a veritable industry, popular as well as scholarly, that churned out numerous (largely conjectural) interpretations of who the Gnostics were and what their texts actually meant. The rise of New Age religions from the late 1970s onward even led a number of groups to adopt contemporary “Gnostic” beliefs and practices that may, or may not, have any actual correlation with what went on in the ancient world. The density and obscurity of the Gnostic writings themselves, deliberately fostered by the elitist and secretive nature of the tight little societies who produced them, encouraged wild and often fanciful scenarios that are as much fiction as fact. Dan Brown’s 2003 runaway best seller *The ► Da Vinci Code*, subsequently made into a movie, for example, propounds the canard that the ancient Gnostics were actually goddess-worshippers who were the true disciples of Jesus, a “secret” tightly guarded and suppressed at all costs by the Catholic Church. There is virtually no historical evidence for any of the suppositions of Brown’s novel, but it illustrates the growing confusion today in the popular understanding of Gnosticism that mirrors a somewhat less, but substantial, divided mind among credible scholars.

The ► *Da Vinci Code* fantasies were, unfortunately, the natural outgrowth of one influential, “revisionist” strand of scholarship that arose among the new breed of feminist academics during the 1980s. In her *The Gnostic Gospels* (1989), which was also a best seller in its own right, Princeton University religion professor Elaine Pagels insisted that Gnosticism merely numbered among various, divergent trends within early Christianity. Pagels actively promoted the view, based on an inferential and not a transparent reading of church history, that Gnosticism did not gain ascendancy in the church and was ultimately stamped out, chiefly because of the persecuting zeal of orthodox clerics, who also happened to be misogynist. Pagel’s arguments, while based on real and plausible circumstantial information, are nevertheless flawed because they confuse outcomes with causal factors. Roman civilization, not just Christianity, was generally misogynist (Christianity of all kinds was far less so than patriarchal paganism),

and there is strong indication that the Gnostics' elevation of the feminine in their curious, baroque forms of mythology was contrary to their real-life contempt for women. The history of religions provides countless examples (especially in the stories and traditions of South Asia) of a religious imagination that exalts the feminine on the one hand, and mistreats them in social custom and practice. This same compensatory mechanism can be found in many feudal contexts.

Much of the current "revisionism" about the sources and significance of Gnosticism turns out to be more a kind of wish-fulfillment than the result of the discovery of any major material artifacts. As is obvious with the outsize popularity of *The ► Da Vinci Code*, the more sensational and counter-traditional a theory turns out to be, the more credibility it seems to garner with a credulous, media-saturated public.

At the same time, Harnack's "acute Hellenization" hypothesis – at least from a scholarly perspective – probably has more going for it than today's pop Gnosticist mania enjoys. Harnack's thread of analysis has ironically in quite recent decades been bolstered by some scholars who look upon Gnosticism not so much as a Christian heresy as a kind of heterodox Judaism that first appeared in Egypt and then spread throughout the Mediterranean world through Hellenization. The leading scholars who have advanced this perspective are Birger Pearson and Kurt Rudolph (1983). In *Judaism, Gnosticism, and Egyptian Christianity* (1990) Pearson showed that not a few motifs from Gnostic cosmology are simple knockoffs from Rabbinic *midrash* – that is, textual interpretation of the Hebrew Bible, or Old Testament. Researchers with this bent have focused on the isomorphism between Jewish apocalyptic literature, which was written as a secret "underground" coded set of communications to those resisting Gentile domination and Gnostic themes, and symbology. The Gnostic preoccupation with ambivalent Scriptural personalities, some perhaps entirely mythical, – for example, Cain, Seth, Enoch, and Judas – offers a hint of this Jewish provenance for Gnostic thinking.

What Harnack referred to "acute Hellenization" had already, therefore, affected Judaism before it had an impact on early Christianity. We know now that Christianity in the first 100 years after the death of Jesus was almost exclusively a form of heterodox Judaism, and with the end of the Jewish establishment in Jerusalem after the two failed revolts against Rome in 66 and 132 A.D., these two heterodox streams most likely merged. Furthermore, it was the non-Jewish factions in the early persecuted church that led the charge against denouncing the "heretics" who came to be called Gnostics. Moreover, the sizable Jewish population in Egypt was far more intellectually influential throughout the empire and among the non-Palestinian Jews, who made up the bulk of the first century. As Judaism declined in prestige after the revolts and Roman persecution became ever more fierce, the dark, pessimistic world view of Gnosticism among the Jewish and Christianized Judaic intelligentsia became increasingly attractive. Inasmuch as Roman authorities had a hard time differentiating Christians in the first two centuries from Jews, the perception that of Gnosticism as a major form of Christianity was not entirely unfounded. The anti-Gnostic movement in the church that putatively resulted in the triumph of "orthodoxy," in fact, may indeed have been part of a widespread *de-Judaizing* trend from the second century onward.

Whereas there is little of what could be legitimately designated "scientific" (other than a reliance on empirical data) in Gnostic studies, one field of investigation that has maintained over the years a certain theoretical rigor is Jungian psychology (Jung and Segal 1992). The movement, which began early in the twentieth century and has burgeoned since the Vietnam era, was an outgrowth of the meticulous clinical investigations and voluminous publications of C.G. Jung, a renegade Swiss disciple of Sigmund Freud who, like his mentor, wrote in German and had a significant impact on avante-garde German-speaking culture right after World War I. Jung rejected complete Freud's "pan-sexual" interpretation of clinical symptoms and postulated in its place a theory of "archetypes" –

universal and ahistorical patterns of imagery and symbolism found in religious rituals, dreams, and myths – that have survived since time immemorial in the collective memory of the human race. It is the job of the psychoanalyst, Jung maintained, to help the patient identify these patterns and to shepherd them skillfully into an integration of the archetypes with the client's own personal experience, a process Jungians have termed "individuation."

But Jung's theories have gone far beyond clinical practice, which remains far more accepted than Freud's to this day. Their central impact has been on not so much myth and ritual studies, including pre-eminently the fields of comparative religions, psychology of religion, and religious studies as a whole in its early phases, as on the investigation of Gnosticism. Jung was enamored with what was known about ancient Gnosticism ever since about the time he broke with Freud on the eve of World War I, and wrote at length throughout his life on the subject.

Indeed, it can be said that Jung fashioned his own version of a neo-Gnostic philosophy or "theology," which was at times hardly distinguishable from his psychological models. Jung closely tied Gnosticism to ancient Egyptian wisdom traditions (known as "hermeticism") as well as to alchemy, a historically dubious association. Within this highly personal conceptual universe Jung evolved from his study of Gnostic texts, Jung was able to elaborate a theory to support his clinical practice of letting the collective unconscious speak and manifest itself to his patients. Jung termed this technique the "active imagination." The active imagination is the Jungian correlate to what Freudians term the "talking cure," where the free-wheeling discourse and insights of the client with the assistance, and sometimes the direct intervention of the analyst, are assumed to generate a self-regulating procedure resulting in psychological growth and healing. Jung was of the opinion, unsupported by any direct evidence from the Gnostic texts or the reports of their critics, that the experience of gnosis was akin to the successes of his own treatment of patients. Jung regarded his own methodology as a "science" (as did Freud) but not in the

sense of modern empirical science, although he was convinced his work with patients yielded immense usable data for the understanding of the human personality and human religion in general. Jung considered his approach a form of *scientia* in the classical meaning of the term – the deliberate and focused pursuit of both general and individual "wisdom" (one translation of the German *Wissenschaft*).

Jungian psychology, at least since the 1930s, has had a negligible effect on Gnostic research. But ironically it has been one of the key ideological underpinnings for popular Gnosticism, which has come to regard itself as an actual religion. As it turns out, some of these "religious" groups have been instrumental in both aggregating and disseminating Gnostic scholarship and writings. The most important of these groups is the Gnostic Society in Los Angeles, founded in 1928 by John and James Priese, theosophists and followers of the Russian mystic Helena Blavatsky. The Gnostic Society, even at present, is centered around the work and ideas of Jung, but its primary mission recently has been to promote ways in which Gnosticism can be cultivated by the average person as a personal religious philosophy and style of life. Dr. Stephen Hoeller, the main luminary and teacher of the Gnostic Society, is also bishop of the Ecclesia Gnostica, which describes itself on its website as "the oldest sacramental Gnostic body in the United States."

Goal Programming

M. Teresa Ortuño

Department of Statistics and Operational Research I, Universidad Complutense de Madrid, Madrid, Spain

Goal programming is a branch of multiobjective optimization, which in turn is a branch of multi-criteria decision analysis (MCDA). Its main characteristic is that for each of the criteria relevant to the problem, a goal or target value to be achieved is established. These values are determined by the decision maker and are usually subjective. Unwanted deviations from this set of target values are then minimized in an achievement function. The technique looks for the satisfaction of the target, not for the optimization of the objective, and then, an underlying satisfying philosophy is assumed. A discussed weakness of goal programming is the possibility to produce solutions that are not Pareto efficient, that is, without the property of not existing other solution not worse for all criteria considered, and better in

at least one criterion. This contradicts the rationality of the decision maker, in choosing an alternative when a better one may exist, difficulty that can be overcome with different techniques.

Description

The role of the denizens of the ancient Indian pantheon in Buddhist texts can in general be understood as part of a tendency to include, albeit in a subordinate position and at times with some significant modifications, central elements of rival institutions or movements into the framework of one's own system.

An instance of such “inclusivism” can be observed in the case of the ancient Indian god Brahmā, who in Buddhist texts features in a plurality of manifestations. The inclusion of the god Brahmā in Buddhist texts occurs in two distinct modes. Several passages mock the claim that a Brahmā could be an all-knowing and eternal creator god, while in other discourses a particular Brahmā acts as a guardian of Buddhism.

The tendency to satirize Brahmā is exemplified in a discourse which professes to explain how the notion of a creator god came into being in the first place. This explanation is based on the ancient Indian cosmological notion that the

world goes through repeated cycles of dissolution and evolution. Once a period of dissolution is over, the *Brahmā* world reappears, and a particular being, in accordance with its merits, is reborn in this world (Carpenter and Rhys Davids 1890–1911, I 17). This being feels lonely and develops a wish for company. In due course of time, other beings are also reborn in this *Brahmā* world, again in accordance with their merits. The living being that arose first in the *Brahmā* world now thinks that his wish for company was the cause for those other beings to come to the same location. This mistaken idea then becomes the basis for the first being's claim that he is the creator of the others, a claim those other beings accept as fact and truth. In this way, the idea of a creator god is parodied as being the outcome of a deluded *Brahmā*'s belief that beings arose in his realm in compliance with his wish for company.

Besides the satirical attitude toward *Brahmā* as a creator, evident in the above passage, the early Buddhist discourses also feature a *Brahmā* in the role of a Buddhist disciple. In a range of texts, the role of this *Brahmā* is to do what he can in order to further the growth and continuity of the Buddha's dispensation. A particularly prominent instance occurs in the Buddha's autobiographical account of his own awakening. According to this account, when the Buddha had just gained awakening, he was hesitant to teach what he had discovered to others. *Brahmā*, who had become aware of the Buddha's disinclination to teach, was alarmed at this prospect and decided to intervene (Trenckner and Chalmers 1888–1896, I 168). He appeared before the Buddha and requested him to teach, proclaiming that there would be those who understand. Following this intervention, the Buddha did indeed decide to teach, so that this episode functions as the starting point of what we now refer to as Buddhism.

The scene of *Brahmā* standing with palms together in reverential salutation to one side of the Buddha who is seated in meditation has become a favorite topic of ancient Indian iconographical representations, vividly illustrating the theme that underlies this episode: the superiority of the

Buddha over *Brahmā* and thereby implicitly of the Buddha's teaching over Brahminical beliefs.

In contrast to this particular *Brahmā*, who behaves as a guardian protector of Buddhism, the devil in Buddhist texts acts as an antagonist to the Buddha and his disciples. The Buddhist devil carries the name *Māra*, a name that literally signifies "death." According to Buddhist cosmology, *Māra* dwells in the highest of the heavens that still belong to the sensual realm, inferior to the celestial realms of the nonsensual heavens, where *Brahmā* dwells. In Buddhist texts, *Māra*'s role is to advocate the enjoyment of sensual pleasures in contrast to renunciation and striving for awakening. The need to defeat *Māra* and to go beyond his reach is therefore a recurrent topic in Buddhist discourse.

In his role as a tempter, *Māra* tries to impede the future Buddha Gotama's progress to awakening by recommending the acquisition of merit and the performance of fire sacrifice instead of striving for liberation (Andersen and Smith 1913, Stanza 426ff). Later tradition presents a more dramatic version of his attempts to prevent the Buddha's awakening. At the head of a frightening army, *Māra* attacks the Buddha-to-be, who in turn calls the goddess earth to witness for his right to remain on the seat where he shall win awakening. This scene became another favorite theme in ancient Indian art.

A series of Buddhist discourses report various attempts by *Māra* to disturb the Buddha and his disciples (Feer 1884–1898, I 103ff). At times, he does so by taking on a frightful appearance, such as a great elephant or a huge snake. Alternatively, he creates a loud noise by shattering some rocks. Such attempts to frighten the Buddha are from the outset doomed to failure, as according to Buddhism a fully awakened one is beyond fear. The same holds for a series of temptations that has *Māra*'s daughters as its protagonists (Feer 1884–1898, I 124). The text reports that they assumed various beautiful shapes in order to arouse sensual desire in the Buddha, the arising of which is similarly held to be an impossibility in the case of one who has reached full awakening.

Māra also accosts Buddhist nuns who are meditating in solitude, trying to tempt them to give up

their life of renunciation and enjoy sensual pleasures instead, or else wanting to confuse them with doctrinal arguments. In each of these instances, he is recognized for being Māra and thereon has to vanish in discomfiture.

It appears to be an invariable pattern that Māra has to disappear as soon as he is recognized by those he is attempting to disturb. Especially remarkable are those episodes which involve attempts to lure arahant nuns or the Buddha with sensuality. Since according to early Buddhist doctrine an arahant has forever eradicated sensual desire, such attempts are from the outset doomed to failure. This would make it clear that in such contexts Māra does not represent a personification of inner defilements. Rather, in these tales, challenges the Buddha and his disciples presumably had to face are represented as the work of Māra. The didactic function of such tales would thus be to indicate by way of example how such challenges should be handled.

In its early Buddhist use, the term “Māra” does not stand just for the individual Māra that lived at the time of the Buddha, but rather represents an “office” that is taken up by a succession of individuals. This reflects the general position taken in Buddhism toward any god or celestial being, in that they are held to be subject to death and rebirth, just like human beings. Thus, an arahant and chief disciple of the Buddha is on record for having in a past life been a Māra himself (Trenckner and Chalmers 1888–1896, I 333). While in early Buddhist texts Māra continues to act as an antagonist of the Buddha and his disciples, according to a later tale, after the Buddha’s passing away Māra is eventually tamed and converted to Buddhism by a fully awakened Buddhist monk (Strong 1992). In this way, with Māra eventually converted and at least one Brahmā acting as a faithful protector of Buddhism, both god and the devil assume their specific Buddhist roles and functions.

Besides Brahmā and Māra, Buddhist thought recognizes a range of other superhuman beings, which up to the present day have their place in local cults in the various Buddhist countries. With the Mahāyāna and especially the Vajrayāna

traditions, the pantheon of such deities expanded by incorporating various celestial bodhisattvas and Buddhas, which serve a variety of functions in a ritual and meditative context.

Related Terms

[Argumentum ad ignoratiam](#); [Deus ex machina](#); [Intelligent design](#)

“God of the gaps” refers to the argument that gaps in scientific knowledge are evidence for God’s existence and direct intervention. One example of the God of the gaps argument is the argument from ignorance or argumentum ad ignoratiam. The argument goes as follows: If a proposition has not been *disproven*, then it cannot be considered false and must therefore be considered true. If a proposition has not been *proven*, then it cannot be considered true and must therefore be considered false. However, this argument is a fallacy, because it says that true things can never be disproven and false things can never be proven but this implies that true things can never be proven and false things can never be disproven.

Today, the God of the gaps argument comes in two variants, namely, an epistemological and an ontological one. The former represents a lack of scientific explanatory power; in other words, more scientific work is needed in order to fill the gaps. The latter, represents a lack of the possibility of falsification; for example, interpretations of quantum mechanics are not amenable to refutation, and so are unscientific. In either case, the use of the term “God of the gaps” is often used in a derogatory sense.

The God of the gaps argument has its roots in ancient Greece. Indeed, dramatists sometimes ended the plot of a story by letting a human-powered vehicle (the machine) appear with an actor or actress on board playing a God or Goddess whose will provides the solution to the difficulties. The play *Orestes* by Euripedes

provides an example. Such a dramatic device was called by the Romans ► *deus ex machina*, god from a machine or vehicle.

The literature refers to Henry Drummond as the one who coined the term. He was a Scottish evangelist. 1894 he wrote:

“There are reverent minds who ceaselessly scan the fields of Nature and the books of Science in search of gaps – gaps which they will fill up with God. As if God lived in the gaps? What view of Nature or of Truth is theirs whose interest in Science is not in what it can explain but in what it cannot, whose quest is ignorance not knowledge, whose daily dread is that the cloud may lift, and who, as darkness melts from this field or from that, begin to tremble for the place of His abode? What needs altering in such finely jealous souls is at once their view of Nature and of God. Nature is God’s writing, and can only tell the truth; God is light, and in Him is no darkness at all” (1894, 333).

Perhaps the most famous example of the God of the gaps argument came about when Isaac Newton considered the question of the long-term stability of the solar system. He was not able to calculate whether the small gravitational forces between pairs of planets would cancel on the average or accumulate. He considered that in the latter case, the unstable behavior would be avoided by the gentle action of God, applying small forces at the right times and places. A century later, Pierre Simon de Laplace showed that the solar system is indeed stable against such perturbations. When his former student, Napoléon Bonaparte, asked why Laplace’s treatise on celestial mechanics did not mention God, Laplace answered “I did not need that hypothesis.”

Another famous example of the God of the gaps argument comes from chemistry at the beginning of the last century.

The question was whether it would be possible to make organic compounds out of inorganic ones. At that time, many believed that inorganic compounds contained some kind of nonmaterial, supernatural life-substance. This theory is known as *Vitalism*. This was so because until then nobody had been able to produce organic compounds out of the inorganic ones. However, this theory was soon to be put aside. Indeed, in 1828,

the German chemist Friedrich Wöhler succeeded in synthesizing urea from inorganic compounds. Once again, God had to retreat.

In more recent times, the gaps in the narrative of biological evolution have sometimes been filled with claims for direct divine action, especially for what concerns human evolution. While most have accepted Darwinian evolution as the principle of the origin of all species including human beings, some accept evolution for plants and other animals, but they reject it for human beings. The advocates of this view lean often on the theory of intelligent design. Irreducible complexity also appears in this context. The argument goes that an organism (such as a cell) has many components, all of which are essential to its proper functioning. Evolution by natural selection of the properties of the organism could not proceed, because there is no intermediate stage that would permit the organism to live (Dembski 1999, 146–49, 237–41).

With the arrival of quantum mechanisms on the scientific scene, the predictability of classical physics gave way to indeterminacy and probabilistic principles. William Pollard suggested that God could influence events in human lives by manipulating outcomes of random events at the atomic or molecular scale. Such small changes can lead to macroscopic results but without making manifest changes in the distribution of large numbers of such events (Pollard 1958, ch. 4).

Chaos theory, the descriptor of classical systems that turn out to have unpredictable long-range behavior, can also be seen as a locus for God's action in areas where detailed explanations are not forthcoming. There have been careful and informed critiques of the approaches of both quantum mechanics and chaos theory to provide the locus of God's action (Polkinghorne 2001, 188–90). Studies along these lines have been made and published with particular attention to avoiding the pitfall of the God of the gaps (Tracy 1995, 290 and especially 320–21).

Grace

Lluís Oviedo
Pontifical University Antonianum, Rome, Italy

Related Terms

[Eternal life](#); [Gift](#); [Love](#); [Mystery](#)

“Grace” is a theological concept within the Christian tradition that broadly expresses the beneficial relationship with the divine. This is hardly a definition, but trying to get closer to the topic becomes a hard endeavor. Indeed harsh discussions characterize the history of this word; it tries to describe a dimension as mysterious as the divine itself; its content is manifold and resists clear unification or distinction. Nevertheless ► [Christianity](#) – and perhaps other universal religions – would lose its identity without this word and the experience it reflects.

In theological terms, the concept of “grace” firstly refers to God, or is associated to His reality, as a source of life and blessing; secondly it is applied to humans and the renewing or regenerating effect consequent to a relationship with the divine. This theology makes sense inside an anthropological framework in which humans are characterized as creatures, and as such, similar to and close to God; as sinners, or limited and subjected to negative drives; and as potentially redeemed and transformed by “grace.” Christian narrative tradition claims that this renewal is rendered possible by Christ’s death and resurrection, and is available to everybody through faith and the means of the Church. However this last sentence might be subjected to confessional disputes. The effects or reach of this divine influence is no less disputed, and the answers span between minimalist solutions, limited to a general “clearance” of ► [sins](#), allowing for eternal life, and a true renewal that points to sanctity or excellence in ► [virtue](#). Furthermore issues concerning grace and personal ► [freedom](#) have been part of this long argument, since some interpretations portray

an idea of grace that substantially limits human freedom.

One essential aspect of the theology of grace is its character of “gift”: It is given by divine dispensation, not deserved because of human merits, efforts, or sacrifices. This aspect is shared by other religions, which point in some of their writings and authors to a similar experience of the divine generosity, “gratis” dispensing its blessing and gifts. The inherent logic of “grace” challenges therefore the dominant logic of rational gain, of self-interest and calculation, of a material view of reality. It sets up a different realm and an alternative perspective that is able to transform everything and to subvert the current order of things. This aspect renders the idea of “grace” clearly counter-intuitive and harder to conceive by a mentality formed on the pattern of rational choice or utility.

The religious idea of “grace” clearly defies some of our most established cognitive schemas, such as the one of agency, and the one of value. Regarding the first, opinions among specialists are divided. On the one hand, the idea of favorable divine action cannot be easily grasped in the current conditions of life in a natural setting. Causes and effects can be seen as merely natural phenomena not requiring a supernatural explanation, which would become something unnecessarily “added” through some psychological trick. On the other hand, cognitivist scholars have pointed to the “agency” or “intentional stance” to explain religious beliefs (McCauley 2011): Some positive surprising events would claim a kind of external agency to understand their unexpected happening and to make sense of that “good luck.” The human mind is so made to such an “agency pattern” that it hardly could assume the existence of very positive and very negative events without such an explanation; without agency they would become unbearable, and would nourish a feeling of excessive contingency. In popular terms, the “nothing happens for nothing” adage expresses a somewhat similar logic.

The second cognitive problem comes from what can be called “value principle”: Things and actions have a value and need to be

recognized as a condition of social order. Thinking in terms of “value” means to be able to account and to decide on the basis of costs and benefits. The idea of “grace” would distort this pattern since it introduces something that has at the same time a great value, but is costless, and as a consequence becomes unmanageable inside a human order of things. This problem finds a solution – always in cognitive terms – pointing to the benefits that could result from an alternative order of things, a form of “reframing” that influences human relationships. In this new frame, the constraints of the value pattern can be overcome or at least momentarily suspended to allow for unaccountable mercy and donation. Its function would be similar to a “psychological buffer” allowing for a view less entrapped in the logic of counting and having, less distressed by the amount of human debt.

This proposed analysis might explain the close link between religious mind and attitude, on the one hand, and the principle of “grace” pointing to divine dependence, on the other. However, the religious mind does not always follow such a schema. Indeed the ideological history of grace reveals tensions with an alternative model of conceiving religious attitude. This different approach resorts to a pattern of exchange, sacrifice, and “trade-like” relationship: The human person gives to God, as a condition to receive blessings or benefits from the Divine. Merit becomes paramount in this model that recovers the logic of value and accounting. A hypothesis arising from this contrast points to the temporal precedence of the “trading pattern” and to the consecutive form of a “religion of grace.” In a similar vein, the first model would reflect a simpler, cognitively easy or comfortable schema, while the idea of grace would represent its “costly form” (Whitehouse 2004). Many tensions inside Christian tradition mirror the intrinsic difficulties at proposing and conceiving a “religion of grace” against a more simple pattern of merit and “trade with the Divine.” Besides this, dangers of disengagement and “free riding” could loom when the message of grace goes too far and completely displaces the idea of merit.

Difficulties at conceiving grace are increased in a more secularized society, in which this idea becomes more and more external to the dominant culture, and to an increasingly scientific mentality. There are nevertheless attempts to translate this traditional notion into more friendly modern categories. New spiritualities, for instance, point to the existence of “positive energies” somewhat available in our environment, and able to transform or to uplift persons. Similarly the idea of “connectedness” that is paramount to new spiritual proposals could be understood as expressing what the old concept of grace made in traditional religions: Being linked to the deep reality, to the “ultimate being” provides positive influence.

Beyond the realm of spiritual developments, the very idea of grace can find other ways to fit into a more scientific and technical worldview. Research in the specialized field of “religious ► [coping](#)” and “religious human flourishing” tries to highlight positive effects of religious attitudes on many aspects of personal and social life. In general, the therapeutic meaning of religious beliefs and practices could be understood as something akin to the idea of grace. This approach might be linked with what in the classic theological jargon was designed as the chapter on “effects of grace.” However, some distinctions need to be kept as a condition to preserve the original content of the concept of “grace.”

Christian spiritual tradition has tried since old times to overcome a too functional or utilitarian conception of divine grace, as something useful to cope with uncertainty and to deal with current dangers and threats. Such a mentality would distort the original meaning of this experience: Grace could become a punctual help matching human interests, and God would become a “provider of benefits” useful for human self-management. The experience of grace is deeply linked to the ones of forgiveness and conversion; this means that the main scope of divine grace is not to supply what is required each time for human self-realization, but to offer a new mentality, a new way of living, away from the old selfish or self-centered condition, and more focused on love of God and other people. Grace

implies a transformation as a condition of its therapeutic effect.

The former statements can suggest an idea of grace as therapeutic instance provided by religious bodies, and in concurrence with other more secular or “technical” therapeutic means. This is hard to assess; in most cases, “grace” does not compete with psychological or physical therapies, but clearly can help healing processes implemented by medical resources. “Grace” cannot be seen as a substitute for standard therapeutic procedures, but as an instance of human renewal or regeneration. Its meaning can be better appreciated inside of a frame of human fullness, or providing purpose, meaning, and reconciliation.

“Grace” is a very specific concept, in the sense that it is clearly placed into the semantics of “transcendence,” as do concepts like God, soul, eternal life, or the sacred. However, some attempts have been made to naturalize it, resorting to the idea of “events of grace” or experiences of “creative transformation” inside an immanent frame (Hardwick 1996). How successful this proposal may be is still a question of time and cultural acceptance; in any case, it seems unlikely that the category of “grace” can survive outside of a horizon of transcendence or the perspective of a divine agent and the cognitive frame of ► [love](#) and donation that God inspires.

The main challenge for theological reflection is perhaps how to update that concept in a cultural context predominantly influenced by a scientific view of reality. The question touches the recent discussion on the levels of “enchantment” and “disenchantment” perceived in Western cultures, a discussion greatly enhanced by Charles Taylor (2007). To perceive a world in sheer physical or material parameters would mean accepting a completely disenchanted reality, something dull and dreary, as Max Weber noted at the beginning of the twentieth century. The idea of “grace” would represent the possibility of opening an alternative space.

The German philosopher Habermas already complained in 1971 that

Philosophy [...] has not been capable of mastering by means of consolation and trust the *de facto* meaninglessness of death in its contingency, that of individual suffering, or that of the private loss of happiness – in general the meaninglessness of the negativity of the risks built into life – in a way that had been possible for the religious hope in salvation.” (Habermas 1971, 17 f)

The religious hope in salvation is a way to speak about grace. The open question is still, four decades after this gloomy prediction, whether developed societies can survive without resorting to a horizon of transcendent grace, just fitting into a complete immanent frame.

The elaboration of the concept of grace might take into account these challenges and try to find new space in the scientifically driven mentality. To this end, some conditions and suggestions can be mentioned.

In the first place, the idea of grace requires some more explicit content in order to connect with modern secular sensitivities, not used to the traditional framework in which such idea made sense and related to a quite well-known Christian horizon. This content has to do with the traditional idea of “salvation,” which becomes problematic as well. Some suggestions come from sociological and psychological studies pointing to religion as a way of “empowerment” and a mean for “human flourishing.” However, it seems that alternative experiences would be more fitting in this case, like the one of forgiveness, of extensive love, or the one suggested by Taylor’s idea of “human fullness” (Taylor 2007). In any case it seems that these proposals remain somewhat fuzzy and require further concretion.

In the second place, the religious proposal of the experience of grace comes in a plural milieu in which many other proposals of full life and love can be found and followed. Its specificity appears to be linked to its predominantly religious character, even its mostly confessional setting in Christian Churches, and its program of reversing one’s own interest and the logic of sheer merit.

In the third place, the concept of grace intends to play a different game, in a different place or with different rules as the one usually played inside the dominant human categories. Here we

have the idea of “displacement,” or of moving into a distinct realm in which our views and experiences acquire specific meaning, to the point of reversing what is usually deemed good and bad. Such a new perspective can provide a way to understand reality in a deeper and more liberating form from the more dominant material perspective. This transformation is not only cognitive, nor just emotional. In a part of Christian tradition, it becomes a dynamic of “divinization” or assuming a condition and orientation closer to how God sees, judges, and behaves.

At the end, what can be proposed under the label of “religious grace” to a scientific mentality is to assume a “variable,” a “factor” that hypothetically can change many things or transform for the best many aspects of a dull and gloomy reality. What counts is what changes or which effect has divine grace as a possible dimension of human reality and the cosmos as we know it; whether this “addiction” can improve things or render them less valuable by themselves. The theological view, deeply engaged with the concept of grace, assumes the wager of looking to reality assuming the presence of transforming divine grace to assess its consequences; or to test the effects of its absence.

Graph Theory

Gómez González Daniel
Universidad Complutense De Madrid, Madrid,
Spain

Description

Graph theory is the field or topic in mathematics related with the study of some particular mathematical structures usually called [▶ graphs](#). Graphs are structures that represent the pairwise relations (usually denoted as links or edges) among a set of elements (usually referred to as nodes or vertices). See Bondy and Murty (2008), for more details about graph theory.

Since the origins of the graph theory in 1736 with the paper written by Leonhard Euler entitled “the Seven Bridges of Königsberg” too many papers have been written in this topic. Some of the most well-known problems in graph theory are routing problems (as the shortest path problem or the traveling salesman problem), covering problems, matching problems, planar graph problems, enumeration problems, network flow problems, visibility graph problems, graph coloring, and partition graph problems. The problems studied in graph theory have had a great impact in the recent years involving different areas; see, for example, Mahadev, N.V.R., and Peled, U.N. (1995), Newman (2006) or Newman (2010). In mathematics, operation research, computer science, logistics, industry, or statistics among other disciplines, graphs are used to model networks of communication, data organization, flow process, control theory, etc. Some examples of the real situations that are studied from the graph theory are (among others) the structure of a website, road transport maps, airplane network routes, train routes problems, and chip design.

Recently, other areas or disciplines have received the attention of the graph theory community as biology (with the development of cellular networks representations), sociology (social networks, the calculation of centrality measures, cohesiveness measure), linguistics (natural language often lends itself well to discrete structure), chemistry and physics (atoms structure underlies in a graph structure), marketing (the diffusion of an idea can be analyzed from a graph theory point of view), and medicine (among other problems, the spread of a particular disease are analyzed from a graph theory point of view). In addition with these recent developments and applications, in pure mathematics, graphs are useful in geometry and topology (see Harary 1967 for more details).

To conclude, it is important to make emphasis again in the importance that has received the study of complex networks in the recent years and the new developments in this research area. The understanding of complex networks and its derived problems is actually a requirement in different disciplines of Science as: sociology (social networks as Facebook, Tuenti, or Twitter among others have a great impact in society), physics (among other disciplines), community detection problems (which requires a sensible decomposition of the graph into subgraphs, where, in some reasonable sense, the nodes in each subgraph have more to do with each other than with outsiders), biology, computer science, medicine, marketing, economics, mathematics, literature, politics, and almost all science disciplines.

Self-Identification

Science

Yes, this discipline/subdiscipline self-identifies as a science. Nevertheless, there are some researchers that consider graph theory as a mathematical science, while others consider it as a branch of mathematics. Because of its focus on applications, graph theory is usually considered to be a distinct mathematical science rather than a branch of mathematics.

Characteristics

Graph theory is distinguished from the other disciplines as mathematics, computer science, or operation research, by its focus on the mathematical structures that can be modeled by means of graph and the problems involve in these structures. Nevertheless, it could be said that actually most of the disciplines of mathematics require the new developments in graph theory for the understanding of the complex networks.

Relevance to Science and Religion

Although mathematics has had a considerable impact in the development of logic and philosophy, which in turn has been very influential in theology, few interest can be founded in “Science and Religion” among graph theory researchers. In order to find some relevant relations among these two topics and taking into account that too many religious symbols as 4-point Star, Star of David, 5-point Star, 6-point Star (Christianity), 6-point Star (Judaism) can be represented as a standard graph, we could include some questions as: What are the mathematical properties of the classical religious symbols? Is there any relation between math & symbols in a similar way as happen with art & math or beauty & math? What have in common the language of religion, arts, and graph theory? Obviously, the possible religious implications of such discoveries are typically not considered professionally by graph theory researchers.

Sources of Authority

The sources of authority in graph theory are the results published in peer-reviewed journals with a relevant impact in the area of graph theory or its applications. Actually, there exist too many journals that deal with the pure and applied impact of the study of graphs. Some of these journals (pure graph journals mainly) among others are: *Discussiones Mathematicae*, *Graph Theory*, *Journal of Graph Theory*, *Journal of*

Combinatorial Theory, Series B, *Graphs and Combinatorics*, *Journal of Graph Algorithms and Applications*, *SIAM Journal on Discrete Mathematics*, *Combinatorics*, *Probability, and Computing*, *Discrete Mathematics*, *Australasian Journal of Combinatorics*, *Ars Combinatoria*, *The Journal of Combinatorial Mathematics and Combinatorial Computing*, *Bulletin of the Institute of Combinatorics and its Applications*, *Discrete Applied Mathematics*, *European Journal of Combinatorics*, *Electronic Journal of Combinatorics*, *Annals of Combinatorics*, *Combinatorica*, *Discrete Mathematics and Theoretical Computer Science*, *SIAM Journal on Computing*, *Diskretnaya Matematika*, *Journal of Combinatorial Theory, Series A*.

The authority of these sources is self-derived by the peer-review process of the researchers more important in the field of graph theory. Some of the more important graph theory pure researchers are (among others): Alon, Noga; Berge, Claude; Bollobás, Béla; Chung, Fan; Dirac, Gabriel Andrew; Erdős, Paul; Euler, Leonhard; Faudree, Ralph; Golumbic, Martin; Graham, Ronald; Harary, Frank; Heawood, Percy John; König, Dénes; Lovász, László; Nešetřil, Jaroslav; Rényi, Alfréd; Ringel, Gerhard; Robertson, Neil; Seymour, Paul; Szemerédi, Endre; Thomas, Robin; Thomassen, Carsten; Turán, Pál; Tutte, W. T.; Whitney, Hassler.

Ethical Principles

As any discipline that affects the human life and improves the quality of the society, nonmaleficence is also an ethical principle for graph theory community.

Key Values

The key values of graph theory are the same that any field in mathematics that are close to the values of publication works in mathematics. The American Mathematical Society, recently resume these key principles in the following

way ...the correct attribution of mathematical results is essential, both because it encourages creativity, by benefiting the creator whose career may depend on the recognition of the work and because it informs the community of when, where, and sometimes how original ideas entered into the chain of mathematical thought. Others key values are thoroughness, rationality, honesty, and curiosity.

Conceptualization

Nature/World

During the nineteenth century, most of the scientists focused their efforts on modeling and accurately modeled many natural phenomena. It is for this reason that many modern historians of science consider the classical deterministic physical, among others, the kings of science during this century. However during the twentieth century, one of the most remarkable discoveries in science was, in my opinion, the complexity of nature/world when you want to model it and understand it. Nothing is easily predictable (e.g., chaos theory) exactly. One of the many factors that make this nature/world terribly complex is the number of relationships between factors, causes, phenomena, ideas that in earlier times were considered unrelated or independent. Graph theory is the natural mathematical tool that allows us to model, analyze, and to change methodologies/previous analysis to take into account that these relationships exist. Many branches of mathematics that model the real world/nature problems have included the graph theory as a key element when it comes to modeling the complexities associated with relationships between entities that were previously considered independent or unrelated.

It can be found that too many disciplines of mathematics have developed different methodologies and models to incorporate the relations that exist among items by means of a graph. For example, in statistics and probability theory, new recent studies have defined “the probabilistic graphical models.” In these models,

a graph represents the conditional independence structure between random variables. Another interesting application can be found in ► [cooperative game theory](#). In this field, usually it is assumed that all the players can communicate without restriction. Recent studies included a standard graph in their models to represent the communication in a more realistic way.

Human Being

The understanding of the human being (specially his mind) has been received too much attention in the Mathematical and Computer Science community. In complex/intelligent systems, it seeks to understand and replicate the learning that takes the human mind to solve complex problems. In this research line, or discipline (among others) we find the neural networks theory (also addressed as ► [Artificial Neural Network](#) theory). Neural network theory has served both to better identify which is the behavior of the neurons in the brain and to provide the basis for efforts to create artificial intelligence. The fundamental-mathematical tools that represent the structure of neural network theory are graphs structures.

Following the fact that graph theory is considered beyond all the strategies that intend to reproduce and understand the human mind, we could conclude that human being (we focus here in the human mind that is what establish the main differences with other species) can be modeled by means of a complex graph.

Life and Death

In mathematics, the Markov Chain models are represented by means of graphs. In this discipline, the terms of life (also denoted as birth) and death is usually addressed with a special case of continuous-time *Markov process* where the states represent the current size of a population and where the transitions are limited to births and deaths. Birth-death processes have many applications in demography, queuing theory, performance engineering, or in biology, for example, to study the evolution of bacteria.

Reality

See section “[Nature/World](#).”

Knowledge

The knowledge is the conclusions or results that you obtain after an empirical study or after some mathematical proofs.

Truth

As in any mathematical discipline, truth is something that is proved (from mathematical point of view) under some assumptions or hypothesis.

Perception

The perception in mathematics is usually addressed as conjecture. Something that could be truth but still is not proved.

Time

Time is a fundamental topic in graph theory. Time is one of the fundamental factors that represent the quality of an algorithm that solves a graph theory problem and also shows the difficulty of the problem that it is solving. In graph theory, a problem is regarded as inherently difficult if its solution requires significant resources of time, whatever the algorithm used. Many of the mathematical models can be classified into hard or nonhard problems depending on the amount of resources needed to solve them, such as time and storage. In terms of ► [computational complexity](#) the problems in graph theory can be divided into P class problems (those problems that can be solved on a *deterministic Turing machine* in polynomial time) and NP class problems (those that can be solved on a nondeterministic Turing machine in polynomial time). For more details, see Garey and Johnson ([1979](#)).

Consciousness

See section “[Human Being](#).”

Rationality/Reason

Rationality is a key topic and concept in mathematics and also in graph theory. Rationality in terms of logic is the way in which the knowledge is built and the truth is found.

Mystery

Mystery is an unusual concept in graph theory. When there exist something that is yet unknown it is usually referred to as open problem, or as a conjecture.

Relevant Themes

An important issue partially addressed in graph theory (especially in artificial neural networks) as regard to “Science and Religion” is the understanding of human mind. The human mind for many researchers is the main difference from the rest of the animal in the world. From a religion point of view, these differences have other explanations (e.g., the soul that the human has instead of any animal). Taking into account the new developments in this area (artificial intelligence could be close to human intelligence in a future) it would be necessary to establish some ethical and moral questions about the differences between “artificial intelligence” and human intelligence.

Taking into account previous problems, in graphs and artificial intelligence it has developed a new discipline addressed as “the ethics of artificial intelligence.” Here it is included the ethics of technology specific to robots and other artificially intelligent beings. Some critics have argued that artificial intelligence has the potential to introduce some new dangers and malaise. For these reasons, there are some researchers that think that there exist some positions/jobs that have to be done by humans as a judge, police, among others. Nevertheless, it is clear for everybody the possible advances that could give us these new methodologies.

Graphs

Gómez González Daniel
Universidad Complutense De Madrid, Madrid,
Spain

In mathematics, a graph is an abstract representation of a set of objects where some pairs of the objects are connected by a relation. The interconnected objects are called vertices, and the relations that connect some pairs of vertices are called edges or links. Typically, a graph is depicted in diagrammatic form as a set of dots for the vertices, joined by lines or curves for the edges. Graphs are one of the objects of study in discrete mathematics. A standard graph is then defined by a set of nodes N and a set on links L . The relations among the nodes in a graph can be directed (asymmetric, then these relations

are usually called as edges) or undirected (symmetric, then these relations are usually called as links).

Related Terms

[Force of attraction](#)

Gravitation is the first type of force according to the way force is defined by modern physics. If you release an apple, it moves toward the ground; hence, there is a force that makes it move that way. The astronomers in the ancient world tried to first record the movement of the stars and then to explain it. It has been quite puzzling (until Galilean times) that on the night sky, there were zillions moving in a regular way, as well as a few other “stars” that were moving in a funny way and that were named after some of the gods of the time – Venus, Mars, Jupiter, and Saturn. One of the main tasks of science about two millennia ago was to describe the motion of the planets. Then, for nearly 1,500 years, not much happened until the time of Copernicus who replaced the Earth by the Sun as the center of the Universe. Soon afterward, Tycho Brahe performed the most accurate measurements of the motion of the stars and the planets of his time. These became the “data set” from which Johannes Kepler deduced his famous laws of planetary motion. And then came Sir Isaac Newton. The simple law of universal gravitation he wrote down not only makes Kepler’s

laws simply a collateral outcome, a matter of mathematical manipulation. Much more importantly, he realized that the force which makes apples fall down and the force which makes the planets revolve around the Sun is one and the same force, the force of gravity.

As far as the forces are concerned, the nineteenth century is the century of electromagnetism with the triumph of Maxwell equations. These equations managed to explain all known electromagnetic phenomena, but they had a major “flaw” – they did not transform properly under the Galilean transformations, they did not respect the law for addition of velocities. Instead, they predicted the existence of a limiting speed, the speed of propagation of the electromagnetic waves and in particular, the speed of light. Well, the story is well known, the Maxwell equations were here to stay, and the Galilean transformations had to give the way to a different procedure for adding velocities, known as the Lorentz transformations. And then Einstein enters into the picture with his special theory of relativity named after the special principle of relativity. The special principle of relativity states that physical laws should be the same in every inertial frame of reference, that is, in all frames of reference, which move with respect to one another with constant velocities. What interests us here is the second part of this definition. What would happen if we compare a physical law in two reference frames, one of which moves with acceleration with respect to the other. After 10 years of hard work, Einstein figured out the answer – nothing would happen if we take into account the force of gravity. The general principle of relativity states that “all systems of reference are equivalent with respect to the formulation of the fundamental laws of physics.” In another words, there does not exist a physical experiment, which will allow us to distinguish motion, say with acceleration $g = 9.8 \text{ m/s}^2$ in deep space away from any massive body and state of rest at Earth’s surface.

This simple statement, through a long line of reasoning, led Einstein to the ideas of curve space-time and to his law of gravitation. This law can be formulated roughly as “the masses of

the objects present tell the space-time how to curve and at the same time the curved space-time tells the objects how to move.” A simple thought experiment, based on the principle of general relativity, tells us that light should bend when passing near a massive object and soon after Einstein’s general theory of relativity was proposed this effect was observed.

One could say that the special theory of relativity of 1905 has two progenies – the general theory of relativity of 1916 and quantum theory with Schrodinger’s equation written down in 1926. And these are the most important, groundbreaking achievements of twentieth-century physics. And for the last already 50 years, the theoretical physicists try to reconcile these two theories or to find a unification, which we will call quantum gravity.

Quantum gravity self-identifies as a science. It is a natural science, part of theoretical physics, dealing with the physical world around us. It should be pointed out, however, that quantum gravity is not a full-scale theory yet. Rather, it could be considered as a long-term project aimed at developing a new physical theory by focusing on the nature of space, time, and the gravitational interaction and intertwining them with a quantum picture of the world. Quantum gravity seeks to find general truths and the operation of all encompassing laws, obtained and verified through the commonly accepted scientific method that is used in the natural sciences and in particular in physics. Although quantum gravity, among all other natural sciences, is, to the biggest extent, concerned with the nature and the beginning of the Universe, it does not consider the Universe as the creation of a superhuman agency; it takes it as all that is and as if there was nothing outside of it (Smolin 2002). In particular, quantum gravity does not contain any moral code, governing the conduct of human affairs other than the one that is typically used in the pursuit of science itself. The issues of life and death in their everyday sense as well as of human ultimate destiny in general are not considered in the theory. The only way these concepts enter into the framework of the discipline is through the question about the

origin of the Universe, which is currently labeled as the Big Bang.

Considered most generally, quantum gravity is a quest for a theory that will, in some appropriate way, unite the two most celebrated achievements of physics of twentieth century, namely, the general theory of relativity and quantum theory. Indeed, almost all of the progress in physics in the last century is grounded in these two theories.

The general theory of relativity led to profound developments in human understanding of the solar system and the Universe as a whole. Now we know a lot about the stars, these mysterious lights on the night sky that have puzzled us from the very dawn of our existence as humans. We know how they are born, how they evolve, while they burn their nuclear fuel, and how they die. We know how they pile into galaxies and galaxy clusters and how all they run away from each other. We even can convincingly speculate on the possible answers to the question about how the Universe came into existence (the Big Bang has become almost a household term).

On the other hand is quantum theory. The theory was developed in order to explain how the world of the small things works, how protons and neutrons combine into nuclei, how electrons wander around these nuclei to form atoms, and how atoms combine into molecules. Quantum theory tells us a lot of puzzling stories, for example, about how atoms, nuclei, and elementary particles manage to behave both as waves and as particles. But we learned how to work with it and managed to reconstruct theoretically the world around us from bottom up. Over the course of the twentieth century, quantum theory has proliferated into a variety of disciplines – from fundamental theories such as those of the electroweak interaction and quantum chromodynamics to the myriads of applications – lasers, microelectronics, and quantum chemistry, to name just a few.

We should say that the two theories are not complete strangers to each other. They have worked together successfully in certain cases. For example, they combine in order to explain how stars produce all the heavier than hydrogen

elements we find in the periodic table, how they mature, and what their ultimate fate is. Yet, these two theories, general relativity and quantum theory, describing one and the same world, are completely different – they speak different languages and produce completely different outcomes. Quantum theory speaks the language of operators and wave functions, of uncertainties and cross-sections, and produces probabilities for various outcomes. General relativity relies on precise geometric constructions like the metric tensor and connections and leads to predictions about the exact trajectories of free-falling observers.

One can say that there is no problem. The two theories have their respective domains, and within those domains, they have achieved profound success. There are certain theoretical considerations as to why some sort of unification should occur, but we can say that currently there is no experimental data that demands univocally that a new theory should replace general relativity and quantum theory. Still, since the middle of the twentieth century, many scientists have undertaken the task of finding a middle ground for the two theories, and a lot of work has been done.

There are two main approaches to find a theory unifying or replacing relativity and quantum theory, which roughly can be classified as (1) the approach of general relativists, who try to quantize gravity, and (2) the approach of the specialists in elementary particle physics who seek a unification of all four fundamental interactions in physics.

The most successful theory in the first approach is the so-called loop quantum gravity (Rovelli 2004; Thiemann 2007; Ashtekar and Lewandowski 2004). It starts from general relativity and repeats the main steps of quantization of a classical system with given coordinates, velocities, and a Lagrangian. Then one defines momenta, performs the transition to a Hamiltonian description, and proceeds with turning the basic coordinates and momenta into operators. There exist various modifications of this procedure, but in all of them, the Schrödinger equation turns out to be represented by some set

of quantum constraints, reflecting the coordinate invariance of the classical theory. Among the main results of this first approach are the definition of geometric operators of area and volume and the introduction of spin-network quantum states where these operators are diagonal. The most successful representative of the other, the elementary particle physicists, approach is string theory (Becker et al. 2007; Greene 2003; Dine 2007), which was recently redefined as the M-theory. It replaces the point particles of ordinary quantum field theory (particles like photons, electrons, etc.) with one-dimensional extended and vibrating objects called strings. The various modes of vibration of the strings correspond to various particles, one of which is the graviton, a massless “spin-two” field propagating on flat Minkowski space-time. String theory aims at describing all four known fundamental forces as well as the matter in a mathematically consistent way. There are other approaches to quantum gravity as well – among those are twistor theory (Witten 2004), noncommutative geometry (Connes 1994), and causal dynamic triangulation (Ambjørn et al. 2008).

But stepping back and looking at the current overall results, we should say that there is a long way to go before we can say that we have built the theory we are looking for. In any case though we can point out at certain features of the theory, whatever it turns out to be. There are two most important differences between quantum gravity and the other natural sciences. The first one is in the way it treats space and time. Most of the natural sciences (with the notable exception of classical general relativity) study their respective subjects assuming that they have on their disposal ever present and all encompassing space and time. We can easily build a reference system using physical objects in order to measure distances and look at the clock on the wall to measure time intervals. In particular, the standard procedure of quantization in conventional quantum mechanics relies on a set up, in which space and time serve as a stage where quantum fields exist and evolve. When we turn to quantization of gravity though, the situation becomes completely different. One of the most important features of

quantum gravity is that in its final form, it should be background independent. Thus, quantum gravity could be considered as a result of a quantization, in which space and time are to be treated in some sense on equal footing with all the other fields.

The second important distinction between quantum gravity and most of the other modern natural sciences is the fact that its predictions cannot easily be verified in an experiment. Simple arguments suggest that because of the nature of gravitational interaction, the effects of quantum gravity would become relevant only in experiments in the so-called Planck regime. In general, all individual particles obey the laws of quantum mechanics, and there are many relevant quantum effects. When we make the transition to large systems of particles, the quantum effects progressively cancel out and the laws of classical physics prevail. In all considerations of quantum mechanics though, we neglect the gravitational interaction altogether. This is because for any two elementary particles, the gravitational force of attraction is much smaller than any other force acting between them, and this is in part because of their small masses. Now, the question is what will happen if we manage to squeeze much larger mass into a region of space which is typically occupied by an elementary particle. The expectation is that the conventional logic is correct – the gravitational interaction will become important, and at the same point, we will need to work within the setup of quantum theory. There is one caveat though, which makes the situation very challenging. A typical length scale corresponding to an elementary particle is its Compton wavelength, which is equal to the wavelength of a photon having energy equal to the particle’s energy at rest, that is, the energy which is due to its mass. It is at this length scale that the quantum effects should be taken into account. The larger the particle’s mass, the smaller its Compton wavelength. But if we try to compress certain mass in smaller and smaller region of space, say corresponding to its Compton wavelength, the gravitational force becomes stronger and stronger, and, at some point, the mass would collapse and form a black hole with a certain characteristic

size which is defined by the so-called Schwarzschild radius. The Schwarzschild radius denoted the radius of a massive spherical object, depending on its mass, such that if the object shrinks beyond this radius, it becomes a black hole. Roughly speaking, the Planck regime corresponds to a situation when the Compton wavelength of a particle becomes approximately equal to its Schwarzschild radius, and in that case, the expectation is that its dynamics would be governed by quantum gravity. Actually, it is believed that quantum gravity will get rid of the commonly expected singularity at the “center” of a black hole or will explain the many unknown processes, which we tend to hide behind the term Big Bang.

The Planck regime is quite inaccessible for any modern or foreseeable in the near future experiment, and this is what makes the development of quantum gravity so difficult – there are no experimental results to guide it. There is a hope though, in the recent years, that the experimental data accumulated via the observation of the Universe with most advanced technologies would provide us with some of the lacking guiding data.

Among the many questions quantum gravity is supposed to answer are those about the beginning (and possibly the end) of the Universe and about the nature of space and time. However, these questions are not analyzed from a religious point of view. In general, people working on the quantization of gravity do not consider it as being relevant to the “science and religion” scholarly area. More specifically, quantum gravity does not try to answer questions it does not pose (Smolin 2002).

As for any natural science, the source of authority for quantum gravity lies within the scientific system of publication of peer-reviewed articles. In case of quantum gravity, these articles contain primarily theoretical derivations and very few, if any, predictions to be verified by experiment. Since currently experiments for verification of the predictions of quantum gravity are impossible to perform, the theoretical constructions that are published are judged in the peer reviews mostly on the basis of mathematical

consistency and noncontradiction with the existing experimental data. Actually, this is one of the most typical and important critiques that are being usually directed at people dealing with quantum gravity research, namely, that they do not produce experimentally verifiable predictions so it is impossible to judge the relevance of their scientific contributions to the “real” physics world.

In general, the ethical principles guiding quantization of gravity are those in place for any theoretical natural science – comprehensive referral to all the scientific sources used in the process of developing the new constructs. Something specific for quantum gravity is the fact that the lack of experimental data and verifiable predictions by the various approaches to quantization of gravity has led to a somewhat strange from an ethical-point-of-view situation. Any modern science requires substantial financing, and in most cases, the financing is related to the effectiveness of solving specific problems. Since in quantum gravity it is difficult to judge objectively the merits of any one of the approaches, the financing is provided on the basis of better marketing and advertisement, rather than on success in experimentally verifying the fundamental laws of nature. As a result, since some of the existing approaches in theoretical physics are much better off financially, many more young people are encouraged to work on them rather than on others. This creates substantial tensions between the approaches. But nevertheless, the key values of quantum gravity are curiosity and determination in pursuing the goal of understanding how nature works at its most fundamental, according to our current understanding, level.

In the framework of quantum gravity, nature comprises of space and time (actually of space-time) and all fundamental elementary particles of matter (fermions) and energy (bosons) entangled in an ever-changing configuration. On the other hand, the human being enters into the considerations of quantum gravity in its role of an observer. In standard quantum theory, unlike in classical physics, the process of observation becomes part of the theory since it influences its predictions – the most famous example of this

situation being the story about the Schrödinger's cat. But still, in the standard quantum theory, the observer can be thought of a human being separated from the system that he or she observes. In quantum gravity, such a separation is impossible, and the observer is part of the picture. To put this simply, in classical theory, the system under study evolves on a fixed stage, observed by the audience. In quantum theory, the stage is still fixed, but the audience participates in the evolution. In classical general relativity, the audience is outside the system and the stage, which evolve together. In quantum gravity, there is nothing fixed and left outside, everything evolves together, and this poses substantial philosophical and technical problems.

Quantum gravity defines the reality as the totality of all objectively existing events and things, which are susceptible to being observed, measured, understood, and explained. It conceptualizes knowledge as the set of all facts or the entirety of truth, information, and principles acquired by humankind via its simple experience or the study of reality. Truth is considered as being the property of a statement of corresponding to or being in accord with reality. Since quantum gravity deals with fundamental questions about space, time, and all physical interactions, some scientists consider it as being the quest for finding the ultimate truth in physics. This is reflected in the fact that string theory has as one of its goals building the theory of everything.

In quantum gravity, perception is considered as being related to the objective reality and as such is a consequence from observations and measurements. While it is understood that it is never complete and always refracted through one's personality, it is also believed that we can strive to make our perception ever closer to the reality.

Time has a special place in quantum gravity, which is quite different from its everyday use. It is one of the main ingredients of space-time, and as such, because of the coordinate invariance of general relativity, time is just a label on events. One of the biggest challenges in quantum gravity

is to extract somehow the usual, familiar to everybody time from the theory.

Quantum gravity relies on the understanding that the physical world can be studied and comprehended outside the concept of consciousness. The consciousness enters into quantum gravity framework only in the sense that in quantum measurements, the observer affects the evolution of the measured quantum system. Rationality is a cornerstone in quantum gravity. It is firmly believed that starting from the established, experimentally tested theories through deep thinking and reasoning a new theory could be developed that will produce verifiable predictions. In quantum gravity, "mystery" is a term used to denote the fact that there is something puzzling, something we do not understand yet. It is generally believed that nothing can prevent science from uncovering the laws of nature. Usually, "mystery" is not used as a term that denotes the impossibility of understanding and describing in scientific terms some finding.

For quantum gravity, as regards "science and religion," the critical issue is the origin of the Universe. Currently, the widely accepted hypothesis among scientists is that some 13.6 billion years, the Universe started with the so-called Big Bang. With this term, we hide our lack of precise understanding as to what exactly had happened at that instant. The expectation is that quantum gravity will provide us with that understanding and eventually would answer the question about the Universe before the Big Bang. Clearly, this theme has direct relevance to the way any religion would talk about the Beginning.

Hadith

Dustin Byrd
Olivet College, Olivet, MI, USA

The hadith are the official collections of Muhammad's sayings and doings. The hadith are viewed as the second most authoritative source of Islamic teachings. They are also used to understand the Qur'an in its proper historical context. Any given hadith can be labeled from *weak* to *authentic* depending on how sure the scholars are that Muhammad actually said and or did what the hadith reports. This oftentimes depends on the strength of the chain of transmission (silsilah).

Description

Happiness can be broadly described as a positive feeling in a subject regarding his/her current life

or state of affairs. This is a subjective sensation or mood linked to the fulfillment of expectations or the achievement of desires, but it can be associated with a state of serenity or internal peace as well. Indeed, part of the difficulty in the study of happiness regards its very fuzzy contours and plural status, which is a consequence of its subjective and to a large extent unverifiable character.

The study of happiness has traditionally been a subject of the philosophical and literary wisdom; religions have often played a role of normative regulation on what should be deemed a good life. In any case, it has until recently been considered a "humanistic topic" (Bok 2010). However, it has become more and more a subject of scientific enquiry, opening the doors to the application of more empirical and experimental methods, providing rigor and data. "Happiness studies" is a well-established field of research that has delivered to this date a considerable amount of essays and specialized papers. Science aims to understand what renders human beings happy, or which factors weigh more in achieving a fulfilling life.

Several interests are involved in this research program, justifying its efforts, as for instance, social policy, educational systems, and even economic planning. Indeed, many governments see as one of their roles facilitating the achievement of the highest levels of life satisfaction for their constituencies. Being such an important and sensitive issue, it is to be expected that the scientific approach enters the arena by providing a large

amount of data, often calling for meta-analysis and in-depth reviewing.

The described interests and the recent arrival of the scientific approach could mean some marginalization of the traditional treatment of the issues related to human life satisfaction. Some disciplines are competing now, when the issue has become less a subject of humanistic and religious study, to offer a better understanding and means for dealing with the general striving for happiness. In any case, the current status of the study of happiness invites deeper analysis and that takes into account the different and sometimes competing perspectives.

The first issue at stake in the study of this complex experience is the semantic one. An interdisciplinary program studying “good life” might help to clarify the ground and to give more accurate descriptions of the terms used and the different contents and ideals referring to the best human aspirations and positive models of life. Indeed, a part of the research is trying to distinguish models and to better understand the characteristics of the main proposals. In that sense, the scientific research on happiness connects with a humanistic tradition deeply concerned with the improvement of human beings. When the ground has been cleared, then the study of the factors involved in the achievement of happiness becomes paramount.

Distinctions and Models

The reader of the abundantly available literature on *happiness studies* will notice that the specialized treatment of this issue points to a fundamental distinction, giving place to what can be called a “dual pattern” of human happiness. The basic distinction discriminates between a subjective concept of happiness, seen as a positive balance in one’s own affects and experiences (*hedonic dimension*), on the one hand, and a more objective and global meaning of personal satisfaction in one’s own existence (*eudemonic dimension*) on the other. The issue is not only semantic but concerns the contents or ideals of good life. On one side, we find the expressivist ideal of living life with intensity, taking advantage of the opportunities to enjoy,

looking for very gratifying experiences, or cultivating satisfying relationships and, at the same time, avoiding pains and sadness. On the other side, we have a model recovering the classical ideal of “virtuous life,” which could be expressed in modern times as “fulfilling life” or “meaningful life.” In this case, we talk about a sense of global satisfaction beyond the passing good moments of pleasure, an experience of gratitude for the whole life, even one assuming negative times and distress into a constructive all-encompassing view.

Even if a consensus has grown regarding the heuristic value of that distinction, scholars devoted to the study of happiness continue to be divided in their focus and the characteristics of each pattern. Many studies report the first model as more selfish and temporal, while the second would be more lasting and generalizable, in the sense of being able to be proposed as ideal for everybody. However, some analysts distrust the embellished image of the eudemonic model, as too fuzzy and indeterminate to be taken as a serious topic for rigorous research (Feldman 2010). The discussion is giving place to two different research programs but still more to applications of this dual model to diverse settings. For example, some authors point to the distinct cultural backgrounds associated with each form: the hedonistic ideal could be associated with a more consumerist and individualist culture while the eudemonic to more socially oriented ideals, presided over by empathy and alternative models of satisfaction. Something similar can be deduced at the level of social policies and the prescriptions that can be deduced from each form for therapeutic practice and educational programs, since both apparently reflect contrasting ideas concerning the human person and social integration. It is not easy to understand both as complementary, since they often may appear as competing ideals of human fulfillment.

At the end, the basic distinction is not only about happiness as something that can be isolated from other human or social dimensions. At issue is an entire conception of life and meaning and purpose in society and morality; in that sense, a circularity arises between ideals of a good life

and its perception or realization between the descriptive and the normative levels and between what is defined and what is looked for. The study of happiness cannot be disconnected from the study of the ultimate questions affecting human nature; and this issue seems hardly distinguishable from social and ethical dimensions.

Factors that Influence the Perceived Happiness

The scientific study of happiness has contributed in large measure to better knowledge regarding which variables might be linked to personal satisfaction. These studies are mainly empirical in method: once indicators of happiness can be isolated or identified through self-assessing surveys, other series of data help to compare variables and calculate correlations between them. Even if this approach presents many limits and can be easily debunked, nevertheless, many lessons can be learned from the large amount of available research papers published in the last 20 years. The following cases make reference rather to the hedonic model, even if not exclusively.

The most studied variables have been income, health, social relations, especially marital state, and work or unemployment. Demographic variables are also considered, like age, gender, and levels of education. The research tries to ascertain in which measure each of these variables affect levels of happiness.

Take income as an example. A lot of research has tried to understand the complexities that link economic income and happiness. The bulk of published papers point to a similar pattern: income has a positive influence in the perceived happiness for those at the lowest level or struggling to cope with their elementary needs. This influence decreases or becomes nonsignificant when earnings increase. From a different perspective, those very happy are unaffected by increases of income. Then this variable weighs in a comparative way: it depends on contexts and forms of life. Discussion arises about which model of happiness would be more related to material income. The intuitive answer points to the hedonistic orientation; however, some studies

reveal that in the long run, earning significantly more than average confers some sense of personal achievement; since in modern societies, income is related to social status.

As could be expected, a positive correlation arises between indicators of health and happiness; perhaps, it is less clear in which direction this positive influence works: is the perceived health what helps to be happy, or is it happiness that renders people more healthy? By the same token, the variable of social capital relates positively with happiness. However, in the case of education, things are more disputed, and the evidence is less clear, even if recent research finds a similar pattern as with income: that variable is relevant in the cases of lowest perceived happiness or for more destitute people.

Several studies point to the great dispersion of happy persons in different societies. It is relatively easy to identify what renders – on average – people unhappy and miserable, but it becomes harder to find broadly shared patterns about what makes most people happy: too many factors appear involved. In other words, even if policies can be designed to tackle forms of unhappiness, it is much harder to find a formula that could ensure happiness for everybody.

Happiness as a Lifestyle

Focusing now on the eudemonistic version, some attempts have been made to better describe what is associated with a fulfilling life, correcting the general or fuzzy elements, and achieving more empirical standards. Carol Riff (1989), for instance, has proposed a widely used model based on six factors that contribute to reaching a good level of life satisfaction. The model is inspired by the tradition of “humanist psychology.” These six points are:

- Self-acceptance
- Positive relations with others
- Autonomy
- Environmental mastery
- Purpose in life
- Personal growth

A second attempt at categorizing this seemingly fuzzy idea of “life satisfaction” reduces the number of factors to four:

- Pursuing intrinsic goals and values for their own sake, including personal growth, relationships, community, and health, rather than extrinsic goals and values, such as wealth, fame, image, and power
- Behaving in autonomous, volitional, or consensual ways, rather than heteronomous or controlled ways
- Being mindful and acting with a sense of awareness
- Behaving in ways that satisfy basic psychological needs for competence, relatedness, and autonomy (Ryan et al. 2008)

The collected data after distributing these questionnaires reveal some interesting patterns about which factors are more dominant in males or females or which age cohorts feel higher levels of satisfaction. The data point to significant variations in time and cultural milieus. For example, in the 1980s, people in their middle age were the most satisfied, while recent surveys show that more mature people appear as the most satisfied. However, some doubts persist. In both models, a mix of self-determination and social aptitudes appear as relevant; the problem is that in real life both goals become less compatible.

Happiness and Religion

In many cases, religion has been considered as a variable influencing happiness. Its absence in the former lists of factors linked to a fulfilling life might be suspicious, but this is part of the problem: is religion involved in that ideal of life? Some studies reveal positive correlations between indicators of religiosity and those of quality of life in the USA (Stark and Maier 2008); the explanations mostly point to the social character of religious activity and its beneficial effects. However, in Europe, the correlations hardly emerge. Take the cases of Denmark and Sweden: both come out as the less religious and the happiest countries in world surveys. In any case, fresh studies propose an influence, on the condition that we assume a slightly different version of happiness: religious intensity influences in a life perceived as purposeful and committed to others, which to some can be considered as “authentic happiness” (Headey et al. 2011).

These results are in line with previous expectations: the religious factor only weighs in a form of happiness, more linked to its set of values, and depends on contexts. It could be stated that Christian faith – and in other religions alike – determines its own pattern of happiness. Religious approaches cannot ignore the value of sacrifice, expiation, and grace, which often get their meaning beyond ideals of happiness. However, even such concepts might be integrated inside a broad program of the pursuit of happiness, or at least of one of its possible and competing versions.

Discussion and Prospective

The current research on happiness offers interesting contributions but at the same time, confronts some limits calling for further revision and a more interdisciplinary approach. The following are a list of questions arising in the reception of the published material.

- “Happiness” is a subjective, hardly observable, concept. As a result, virtually all scientific data on human happiness is based on self-report, which is subject to self-deception and therefore becomes less reliable. Nevertheless, some efforts have been made to correct that restraint, for example, resorting to hormonal indicators and neurotransmitters associated to well-being.
- There are too many factors involved in trying to measure happiness, an increasing complexity that cannot be reduced to few variables; people can feel happy even in harsh conditions.
- The empirical approach has to recognize that happiness continues to be a too elusive concept, and its statistical treatment becomes of limited scope, requiring hermeneutic analysis or taking into account the cultural background allowing for a better understanding of what renders people happy in some place and time.
- There is a suspicious absence of the dimension of alterity: often our happiness depends strongly from the happiness of people close to us; the problem is broader and reflects the flaws of a too reductionist program.
- The consequences at the normative level are dubious; should we opine about which kind of

happiness is better? Should we discourage some of them as too selfish?

Relevance of Happiness for Science and Religions Dialogue

The scientific approach provides interesting data but can hardly displace or substitute some other forms of traditional wisdom related to this topic. From a theological point of view, however, more needs to be done to integrate this knowledge into an updating of the Christianity's and other religions' promise of salvation. Or, by the same token, more needs to be done by the scientific program to integrate traditional religious contributions.

The question is how useful all of this corpus of scientific research on the correlates and causes of human happiness is for theology and religion in general? At first sight, its relevance is apparent: theology deals with salvation, and whatever the meaning of this term is, the usual understanding of happiness and a good life, and the means to achieve them cannot be left outside the theological vision as to what is believed to "save" humans and render them better off. On the other hand, some apprehension may be justified. Theological concepts about salvation belong to a rather different "linguistic game," to say the least, as compared to the semantics of happiness and the secular ideals of a good life. However, this is part of the problem: whether this is the case, whether we can really develop a theology of salvation apart from a consideration of the empirical factors helping to live a better and full life, or to overcome suffering and misery. As happens in many other settings, theology divides between a more intratextual, self-referential approach; and a more open, externally related effort of steady dialogue with contemporary reason. This second approach could obtain some advantages engaging in a constructive dialogue with the empirical, scientific happiness studies.

Probably, the scientific treatment of happiness and a good life can supply theological reflection with an interesting input when theologians try to update and renew the Christian discourse on salvation; the same can be said concerning other religious proposals. This is a point badly needed, since

the meaning of the Christian promises of salvation fades away, once departed from their former dominant eschatological dimension. This revision or latent dropping of more eschatological views are not the only causes of concern affecting Christian promises. Furthermore, the attempts of politically inspired theologies that aim to overcome material and socially unbearable conditions collapse when they come close to western environments with higher levels of equality and good welfare systems; salvation cannot in that context be described in terms of material collective improvement; such strategy soon becomes redundant. The great challenge now for theology is to adjust the message of salvation to the social and cultural conditions of advanced societies, with different sources of concern and distinct and varying aspirations. Knowing more about these issues might help to make better and more fitting answers.

In any case, the religious reception of happiness studies needs to be nuanced. As a first step, it is necessary to account for a spectrum of models of happiness beyond the reductive dual model; such spectrum could range between the extremes of pleasure born from satisfying desires, and Buddhist appeals to silencing desires. Then, second, there are some insights from Christian tradition, which can correct some one-sided views; issues like guilt or moral failure are apparently aspects deeply related to a good life and ignored in the current treatment. In this sense, religious views can help to complement the reductive program of scientific research and offer insights from their wisdom traditions, of value beyond historical contexts.

Hegel's Thesis-Antithesis-Synthesis Model

Sarah A. Schnitker¹ and Robert A. Emmons²

¹School of Psychology, Fuller Theological Seminary, Pasadena, CA, USA

²Psychology Department, University of California, Davis, Davis, CA, USA

A dialectic method of historical and philosophical progress that postulates (1) a beginning proposition called a thesis, (2) a negation of that thesis called the antithesis, and (3) a synthesis whereby the two conflicting ideas are reconciled to form a new proposition. Although this method is commonly referred to as the Hegelian dialectic, Hegel actually attributed the terminology to Immanuel Kant. Moreover, many scholars argue that the dialectic is represented of German idealism as developed by Johann Gottlieb Fichte.

Hegemony

Jill Dierberg¹ and Lynn Schofield Clark²

¹Communication and Digital Media, Carthage College, WI, USA

²University of Denver, Denver, CO, USA

Imperial domination by one group over another. Antonio Gramsci refers specifically to cultural hegemony, which refers to domination by one social class over another through the manipulation of mainstream society's beliefs about social norms and values, which subsequently contributes to a dominant worldview that reinforces the status quo.

Heisenberg's Uncertainty Principle

Russell Stannard
Department of Physics and Astronomy,
Open University, Milton Keynes, UK

The uncertainty principle is the recognition that a precise, simultaneous measurement of some complementary variables - such as the position and momentum of a subatomic particle, or its energy and the time at which the energy was measured - is impossible. Contrary to the principles of classical physics, the simultaneous measurement of such variables is inescapably limited; the more precisely one is measured, the less one can learn about the other. One of the consequences of this is that one can have small fluctuations in energy for short periods of time.

Hermeneutics and Hermeneutic Philosophy

Karsten R. Stueber
Department of Philosophy, College of the
Holy Cross, Worcester, MA, USA

Hermeneutics is the theory of interpretation concerned with a theoretical exploration of the manner in which we grasp the significance or meaning of texts, utterances, or actions. Hermeneutic philosophers from the nineteenth century onward generally think that the human sciences concerned with facts of significance and meaning has to be methodologically distinguished from the natural sciences. Traditionally, this distinction has been expressed as the distinction between understanding versus explanation.

The Problem of Hermeneutics

The word “hermeneutics” can be etymologically linked to the Greek verb *hermeneuô* and the Greek noun *hermeneia*. *Hermeneuô* refers to the

act of explaining, expressing, and translating; *hermeneia* is an interpretation or translation. The word “hermeneutics” can also be linked to Hermes, who was in Greek mythology the messenger of the gods and the one who not only transmitted but also explained or translated their messages for humankind. The verb *hermeneuō* thus refers to activities which are typical for all human beings. Humans are interpreting beings, that is, beings that experience consciously, interpret their experiences, try to give meaning to them, and express these interpretations and meanings in language. In a certain sense, the whole of human culture can be understood as the outcome of the interpreting way of existing that is so typical for humankind. “Hermeneutics” is then the discipline that reflects on human beings qua interpretative. It is an interpretation theory. As such, it is of course at least as old as Western civilization. The need for hermeneutics emerges from the moment a culture ascribes authority to a body of texts which are handed down from the past. For, when a culture does this, it is unavoidably confronted with the problem of the gap which separates present-day readers of these authoritative texts from the time and context in which these texts were written down. This gap results from the fact that history inevitably goes on and that things inescapably change. As a result, presuppositions of the authors of a culture’s authoritative texts are most often no longer shared by those who read the texts in a later age, and things which were self-evident and unquestionable at the time that the texts came into being have become strange and objectionable for later readers. But precisely in so far as a culture’s identity is founded on these texts that shape private and public life to a considerable degree, it cannot simply dismiss them as distant relics of the past without relevance to the present. This is why the issue of how these texts should be interpreted and understood becomes inescapable. This happened in ancient Greece, where the age-old narratives, and in particular Homer’s work, were judged by later generations to contain acts that were morally reprehensible. The same was the case in Alexandria among educated Jews, like Philo

of Alexandria (c. 25 BCE–50 CE), who felt uneasy about the all too anthropomorphic picture of God in their Scriptures. Also, the rabbis were confronted with the issue of how to apply the Scriptures to the present-day situation, which often posed new challenges unknown at the time when the texts were first written down. It may not come as a surprise then that, both in ancient Greece and in Judaism, hermeneutics emerged, that is, reflection on how to interpret authoritative texts. Christianity, in which the Greek and Jewish heritage merged, of course inherited the problem of how to interpret old texts, especially because it claims to offer a *new* interpretation of the Hebrew Scriptures in light of the Christ event. Early Christian reflection on this issue eventually culminated in the publication of *De doctrina christiana* by Augustine (354–430). (For an extensive overview of the early history of hermeneutics, see the second chapter of (Jeanrond 1991).)

The Emergence of Philosophical Hermeneutics and the Transition to a Hermeneutical Philosophy

Until the end of the eighteenth century, there were a number of specialized hermeneutics, each with a rather limited scope and concerned with formulating rules to guide the interpretation of a particular set of texts. Biblical hermeneutics, for instance, dealt with the interpretation of biblical texts, and legal hermeneutics dealt with legal texts. It was thought that the special character of, for instance, the biblical text as revealed by God necessitated separate rules to interpret it. This changed with Friedrich Schleiermacher (1768–1834) who conceived hermeneutics as the discipline which should deal with the understanding of texts *in general* and who denied the need for a special hermeneutics when reading the Bible: no matter whether we read a biblical text or any other text, the same rules should apply. This also entails that the hermeneutical problem, as we have sketched out in the previous section, pops up, not only when we read certain authoritative or classic texts, but each time when we read a text.

Or, to put it differently, the hermeneutical problem has a universal scope, and therefore we need a general theory of what it means to understand a text. Schleiermacher was the first to offer such a theory and can, for this reason, be designated as the grandfather of contemporary hermeneutics. Yet, this innovation remained relatively unnoticed, and it was only toward the end of the nineteenth century that hermeneutics as a *general* theory of understanding was revived. This was the merit of Wilhelm Dilthey (1833–1911), who conceived hermeneutics as a foundational theory for all the humanities (in German: *Geisteswissenschaften*, in French: *les sciences humaines*), a foundation which was urgently needed to be able to respond to the impact of the natural sciences, which understood themselves as the only way to truth and objective knowledge, dismissing the humanities as inferior disciplines. Dilthey attempted to secure a role for the *Geisteswissenschaften* by distinguishing between their supreme *verstehen* (interpretative understanding) and the ordinary *erklären* (causal explanation) of the natural sciences. The concern to counter nineteenth-century positivism was also shared by Edmund Husserl (1859–1938), the founder of phenomenology, who attempted to safeguard the independence of philosophy via the claim that philosophy should concern itself with the role played by the human subject in the constitution of *all* knowledge, both in the humanities and in the natural sciences. Phenomenology was transformed into a completely hermeneutical philosophy by Martin Heidegger (1889–1976), Husserl's most important student. It was Heidegger who established hermeneutics as we know it today. Many basic ideas that are common sense for hermeneutical thinkers were developed by Heidegger. In this regard, we can, for instance, refer to the view of language as not merely an instrument to express prelinguistic thoughts but as the very medium of thinking itself and to the stress on the decisive role of presuppositions in understanding as well as the circular character of understanding, the so-called hermeneutical circle (see below Section “[The Hermeneutics Circle](#)”). This suggests that if Schleiermacher was the grandfather of contemporary hermeneutics,

Heidegger was its father. After Heidegger, hermeneutics was developed further, first, by Heidegger's disciple Hans-Georg Gadamer (1900–2002) and, subsequently, by Paul Ricœur (1913–2005). Ricœur's merit was that he developed a hermeneutics that aims at recovering the meaning of the tradition (as Gadamer aimed to do as well) while also being critical of the tradition. This move beyond Gadamer had become necessary by the critique of Jürgen Habermas (b. 1929). According to Habermas, Gadamer's hermeneutics ran the risk of merely continuing the oppressing elements of tradition. (For further details on Schleiermacher, Dilthey, Heidegger, Gadamer, and Ricœur, see Chap. 3 of (Jeanron [1991](#)).) A prominent contemporary hermeneutical philosopher is Gianni Vattimo (b. 1936), who draws on the work of Heidegger, Nietzsche, and Gadamer.

The Emergence of a Hermeneutical Theology

Hermeneutics and Christian theology are inextricably bound up with each other. As previously noted, Christianity was, from its beginnings, confronted with the question how the texts of the Bible were to be understood. Yet, a theology which explicitly understands itself as being hermeneutical has only come into existence in the course of modernity when, thanks to the work of the aforementioned philosophers, continental philosophy became conscious of the linguistic character of every experience of reality. As a result, hermeneutics is no longer the specialized study of particular texts (as it was before Schleiermacher) and also no longer that part of philosophy which concerns itself with the study of the interpretation of texts in general (as it still was for Schleiermacher), but the discipline which makes clear that humans are interpretative beings, that being human means living an interpreting existence (cf. Section “[The Problem of Hermeneutics](#)”). In the wake of the developments wrought by the aforementioned philosophers, Christian theologies that explicitly understand themselves as hermeneutical have

also come into being. This first happened in the Protestant tradition, with the first major step in this direction having been taken by the Lutheran theologian Rudolf Bultmann (1884–1976), who fell back on Schleiermacher, Dilthey, and Heidegger. Bultmann has presented the basic principles of his hermeneutical theology in an article which was published in 1950 in the *Zeitschrift für Theologie und Kirche* (Rudolf 1950). Following the lead of Bultmann and his disciples, like Ernst Fuchs (1903–1983) and Gerhard Ebeling (1912–2001), as well as in the wake of the Second Vatican Council (1962–1965) in its turn to the world, hermeneutical theologies also came into being among Catholic theologians. In this respect, we can refer to Edward Schillebeeckx (1914–2009) (Schillebeeckx 1972), Francis Schüssler Fiorenza (Schüssler Fiorenza 2002), and David Tracy (Tracy 1989). More recent developments include Ricœur becoming the most important source of inspiration for hermeneutical theologians (cf. Geffré (1983) and Geffré (2001)) and the impact of deconstructionist thought, which was founded by Jacques Derrida (1930–2004) and has given rise to attempts, by, for instance, John D. Caputo (Caputo 1987) and Caputo (2000) and Richard Kearney (Kearney 2001), to integrate deconstructionism into the legacy of hermeneutics. Against this, other theologians, like Lieven Boeve, have defended that these attempts are not radically hermeneutical enough because they do not take sufficiently into account the particularity of religious narratives and traditions. Being radically hermeneutical entails, Boeve claims, that the deconstructionist search for universal, but empty and formal, structures should be abandoned. Religious truth happens, not despite of, but thanks to particularity (Boeve et al. 2005). This does not mean, however, that all theologians have adopted philosophical hermeneutics/hermeneutical philosophy. Ever since Karl Barth (1886–1968) rejected the hermeneutical tradition begun by Schleiermacher because he considered it to be a threat for the recognition of the Bible as God's self-revelation, there has been a strong line of theologians denying the importance of a general, philosophical hermeneutics

or hermeneutical philosophy for theology. As pointed out by Jeanrond, even Bultmann's students Fuchs and Ebeling moved in the direction of a Barthian "inner-theological hermeneutics." (For the debate between Bultmann and Barth on hermeneutics and its aftermath, see Chap. 6 of (Jeanrond 1991).) In the same line, we can also situate George Lindbeck (b. 1923), Hans Frei (1922–1988), and other theologians connected to the so-called Yale School of theology, all of whom reject the Enlightenment belief in the universality of reason which would enable *Verständigung* (agreement) across all borders. Of course, this does not mean that these theologians do not accept the need for interpretation, but they claim that theologians should concern themselves with a *specifically theological* hermeneutics, which aims at the *intra-textual* interpretation of Christian texts. (See for further details on this Sect. 7.1 in Jeanrond (1991) and Schüssler Fiorenza (2002).) Moreover, the rejection of the universalist claims of reason and the stress on the irreducible particularity of religious narratives and traditions would probably also be shared by many theologians, like Boeve (Boeve 2005), who nonetheless, to put it in the words of Jeanrond, "favour an open-ended dialogue between Christian interpreters and other thinkers interested in hermeneutics" (Jeanrond 1991). This suggests that the distinction in contemporary theology between a "Bultmannian" line (which holds on to the attempt to reach universal *Verständigung*) and a "Barthian" line (which stresses the specificity of the Christian "grammar") should not be considered as being absolute. While Christians may in fact use a particular grammar, this does not entail that they should not try to reach *Verständigung* with non-Christians: it is always possible to translate. But this is only possible to a certain degree: absolute *Verständigung* is impossible. A language can never be rendered into another without at least some of the nuances or meanings being lost. The same is the case with Christianity: Christians can and should explain what is at stake in Christianity but can only do so to a certain degree; to grasp what it is all about in Christianity, one has to experience Christianity *from within*. The distinction between the

“Bultmannian” and “Barthian” line then concerns a different emphasis: “Bultmannians” will stress the explainability of Christianity while “Barthians” will stress what remains inexplicable for those who are not involved in the mystery of which Christianity speaks.

The Hermeneutical Circle

One of the most important concepts, if not the most important concept of philosophical hermeneutics as it has been adopted by the hermeneutical theologians is without doubt that of the “hermeneutical circle.” (a) In a primary and restricted sense, the concept refers to the dialectic between the whole of a text and its parts: we can only understand the whole of a text by reading its different parts but at the same time the different parts only receive their meaning by their place in the whole. This suggests that the “whole” and its “parts” both inform and elucidate the other and as a consequence, what we have here is actually a never-ending hermeneutical spiral. (b) In its general sense, however, the hermeneutical circle/spiral refers to the interaction between a text and its readers. Readers cannot but approach a text from their particular pre-understanding, that is, their questions, concerns, expectations, and prejudices, which will color how they will read the text. On the other hand, however, a text always has a certain objectivity and therefore resists to a certain degree to our attempts to mold it completely in line with our pre-understanding: there are limits to the interpretations allowed by the text. This is what hermeneutics means when it speaks about reading as a “transformative” act: by reading a text, that text questions and changes our pre-understanding. Furthermore, what is the case when we read a text is also applicable with what we experience in general. Hermeneutics rejects any clear-cut distinction between experience and interpretation and stresses that experience and interpretation go together: experiencing is always interpreting, when we experience reality we do so from within a particular pre-understanding. It is not the case

that we first experience “pure,” “non-interpreted” facts and that only afterward, we integrate these facts into a theory or frame of interpretation. It is precisely the other way around: what we experience as facts is to a large degree determined by the theory with which we approach the world. Most often, we only see what we are expecting to see or have learnt to see. The knowledge we already have acquired, the models, schemes, and categories which we already have and which are the result of previous experiences, determine the way we approach the world, and we will always attempt to integrate new experiences in that already-existing framework. But at the same time, experiences also challenge our frame of interpretation and this sometimes to such a degree that only a radical reorientation of that frame makes it possible to deal with the newness we experience. All this shows that hermeneutics rejects any naïve empiricism which considers the human mind as a “mirror of nature,” while, on the other hand, not falling victim to a pure subjectivism and relativism because it accepts the stubbornness of reality, which cannot be reduced to whatever we make of it but always continues to question our interpretations and theories. (c) The hermeneutical circle can also be applied to the relation between a religious tradition and contemporary religious experiences. From the given that experience and interpretation always go together, it follows that the distinction between a believer and a nonbeliever is not merely a matter of interpreting the same experiences differently, as if the believer and the nonbeliever share the same experiences and the believer, in contrast to the nonbeliever, is making all kinds of fanciful interpretations of what he or she experiences. To a certain degree, the believer and the nonbeliever have different experiences because they approach the world from within different frames of interpretation. This shows that a religious frame of interpretation is important in order to have religious experiences: religious experiences do not occur out of the blue but can only take place when people share in a tradition which gives them a religious way of looking at things. This entails that being part of a community in which a religious narrative is

brought into practice is of utmost importance to have religious experiences.

Hermeneutics and Natural Science

As the examples of Dilthey and Husserl suggest, the hermeneutical tradition is rooted in a countermovement against the all-pervading scientism of the Enlightenment as it reigned supreme in the positivism of the nineteenth century. Hermeneutics began as part of Romanticism, which was an attempt to protect the daily life world and the reflection on it against the invasion by a modern natural science which understood itself in an aggressive way as the sole way to truth and objectivity. As the examples of Dilthey and Husserl show, hermeneutics did this by making the natural-scientific understanding of truth in terms of objectivity and correspondence subservient to a more original and more fundamental type of truth which can only be grasped by the philosopher. This kind of distinction is also to be found in the work of Heidegger, who considered truth qua correspondence between proposition and thing as only a secondary type of truth, subsidiary to a more fundamental truth qua *Weltoffenheit*, that is, truth qua horizon in which the many factual truths can appear. When Gadamer adopted Heidegger's distinction between truth as opening and truth as correspondence, he did this in order to confirm, as Dilthey and Husserl had done before him, the superiority of the humanities vis-à-vis the natural sciences, who are in need of legitimization by "a thinking which relates them back to the *logos*, to the common consciousness expressed in the natural-historic language of a society and in its shared culture, whose continuity . . . is assured precisely by the human sciences and by philosophy in particular" (Vattimo 1994). In this way, however, Gadamer leaves unquestioned the opposition between *Naturwissenschaften* and *Geisteswissenschaften*, and, by doing so, he actually subscribes to the positivist-Enlightenment view of science which considers the natural sciences to be an exceptional human activity, though it is, according to Gadamer, an

activity which has to be controlled by practical reason. Neither does Ricoeur question the distinction between exact and interpretative sciences because his hermeneutical method is explicitly developed with only the humanities in mind (O'Murchadha 1997). It is, however, precisely the very opposition between natural science as exact and the humanities as interpretative that has become questionable today. This is the case because recent developments have shown that the positivist-Enlightenment view of science is no longer tenable, though it still is the way many scientists and ordinary people think of science. The positivist-Enlightenment view entailed the conviction that science is the "mirror of nature" which offers humankind a unique and privileged access to reality as it really is in itself. Science was thought by the positivists to be an exceptional human activity: a disinterested search for knowledge, objective, neutral, value-free, and primarily theoretical-conceptual. A first development which contributed to the problematization of this rather naïve view of science was the work of a number of philosophers of science in the Anglo-Saxon tradition, namely, Karl Popper (1902–1994), Thomas Kuhn (1922–1996), Imre Lakatos (1922–1974), and Paul Feyerabend (1924–1994). For instance, Kuhn, in his *The Structures of Scientific Revolutions* (1962), negated the common view of science as the linear accumulation of ever more accurate knowledge. Instead, he defended the view that in the development of science periods in which scientists work within a paradigm alternate with periods of crisis in which a paradigm shift takes place. These ideas of paradigms and paradigm shifts have been applied to the history of theology by Hans Küng and have also been linked to Heidegger's truth as opening. Also, the development of the so-called science studies, which investigate science from a sociological, historical, and/or cultural perspective, has contributed to the critique of the positivist-Enlightenment view of science. It is argued that the sciences have not developed in isolation from their historical, political, social, and cultural context and that such sciences are not so objective, neutral, and value-free as the positivist-Enlightenment view

naïvely thought. The critiques have even gone so far as to claim that science is actually deeply gender-biased and Eurocentric. This post-positivist view of science, which has come into being in the wake of the aforementioned developments in contemporary thought, suggests that it is no longer possible nor desirable to uphold the traditional distinction between *Naturwissenschaften* and *Geisteswissenschaften* when it comes to their interpretative character. Fundamental insights of hermeneutics – such as the impossibility of a noninvolved neutral observer, the theory-ladenness of all observation and experimentation as well as the nonexistence of “pure” facts (see Section “[The Hermeneutical Circle](#)” above) – not only apply for the humanities but for the positive sciences as well. Despite this, however, contributions in forming a hermeneutical philosophy of science (by, for instance, Joseph Kockelmans and Patrick Heelan) have not yet entered mainstream philosophy of science and have until today remained largely invisible for the broader philosophical and theological community. (For examples of philosophical reflection on science from a hermeneutical point of view, see, for instance, Kockelmans (1993), Crease (1997), Ginev (1997), Heelan (1998), Fehér et al. (1999), Ihde (1999), Babich (2002), Kockelmans (2002), Eger (2006)).

Science and Religion from a Hermeneutical-Theological Perspective

The conclusion that even natural science shares in the interpretative character of human existence also unfolds a new perspective on the so-called conflict between science and religion. In particular, the interpretative character of natural science is bringing natural science and religion much closer to each other than ever possible within a positivist view. Rather than considering natural science as the sole way to objectivity, truth, and knowledge on the basis of which we have to dismiss religion as belonging to an earlier phase of human civilization, we have to

recognize science and religion as two activities of humankind by which it attempts to deal with the mystery of its being in this world. This suggests that at the basis of both science and religion is a shared sense of wonder and amazement. In this respect, we can speak, following Boeve, of “a ‘kind of unity in tension’ that characterizes both faith and science, that is, a fundamental passivity, openness, receptivity, which drives both faith and science forward.” Science and religion, moreover, also share another structural similarity, namely, their “pathos for truth, the urge to search for meaning and understanding.” At the same time, however, a hermeneutical-theological perspective on the relation between science and religion will also stress the irreducible “specificity and incommensurability” of both. They may both be interpretative enterprises which share their sense of wonder and pathos for the truth; this does not mean that we should strive for an integration of them. This suggests that a hermeneutical-theological perspective on the relation between science and religion only allows for a moderate or limited dialogue between science and religion, that is, a dialogue that limits itself “to situat[ing] the independence of both language registers while seeking structural affinities.” Only in this way, Boeve claims, unnecessary conflict between and hegemonic unity of science and religion can be avoided, and he concludes that what the dialogue between science and religion has to do is “to reflect . . . on what it means to be a human person in today’s multifaceted world” (Boeve 2007).

Hierarchy

Stanley N. Salthe

Department of Biological Sciences, Binghamton University, Binghamton, NY, USA

Hierarchies order entities, processes, or realms into a system of levels. The ordering principle ("is-a-part-of" for the *compositional hierarchy* and "is-a-kind-of" for the *subsumptive hierarchy*) is transitive across levels. In both of these hierarchies, when used to model systems, higher

levels control (regulate, interpret, integrate, harness) lower levels, whose behaviors are made possible by properties generated at still lower levels. It is important to realize that only some users of hierarchical forms would insist that particular levels exist in actuality. Levels are discerned from hierarchical analysis, aimed at discovering Nature's "joints" with respect to given projects.

Description

The approach taken in the Buddhist traditions to meditation and mental culture is fairly methodical, a feature exemplified in the singling out of specific mental states or conditions as "hindrances" to the cultivation of meditative calm and insight (► [Buddhist Meditation Practices](#)). Buddhist texts identify five particular mental states as "hindrances," in the sense that these five prevent the gaining of deeper levels of

concentration and therewith also obstruct the growth of wisdom. The presence of any of these five hindrances is held to obstruct the proper functioning of the mind to such an extent as to make it difficult to remember properly what happened earlier or to understand what is for one's own benefit or for the benefit of others.

The standard list of these hindrances to the development of meditation covers the following five:

- Sensual desire
- Ill will
- Sloth and torpor
- Restlessness and worry
- Doubt

The above listing of five hindrances actually comprises seven distinct mental qualities. The circumstance that these are subsumed under a fivefold presentation would be due to the similarity in effect on the mind of sloth and torpor as well as of restlessness and worry.

The nature of these five hindrances finds illustration in two sets of similes. The first set depicts a bowl filled with water that is used to see the reflection of one's own face (Feer 1884–1898, V, 121). In the context of this simile, the effect of sensual desire is similar to water that is mixed with dye, ill will resembles water that is heated up and boiling, sloth and torpor is comparable to water overgrown with algae, restlessness and worry is like water stirred by the wind, and doubt is like muddy water placed in the dark. In each of these five cases, one is unable properly to see the reflection of one's own face.

This set of similes thus illustrates the effect each hindrance has on the mind: sensual desire colors the way one perceives things, with ill will one gets quite literally heated up, sloth and torpor result in stagnation, restlessness and worry toss the mind around, and doubt obscures.

The other set of similes illustrates the absence of the hindrances (Carpenter and Rhys Davids 1890–1911, I, 71). In this set, overcoming sensual desire is compared to being relieved from debt; removing ill will is like recovering from a disease; abandoning sloth and torpor is similar to being released from prison; going beyond

restlessness and worry is as if one has been liberated from slavery; and leaving behind doubt is akin to having crossed a dangerous desert safely.

In this way, this set of similes indicates that sensual desire affects the mind comparable to being heavily in debt, ill will afflicts body and mind like a disease, sloth and torpor imprison the mind, the agitation of restlessness and worry can completely control the mind, and doubt leaves one in a condition of deplorable insecurity.

In the case of the first of these five hindrances, according to Buddhist meditation theory, close inspection shows that sensual desire arises not simply because of external stimulation, but to a considerable extent is the outcome of an inclination of the mind toward searching for satisfaction in sensual pleasures. The dynamic of sensual desire is such that, with every instant of its satisfaction, the tendency to have sensual desire becomes strengthened. Hence, the way to inner peace, according to the early Buddhist analysis, requires overcoming this never-ending vortex of desire and gratification and thereby gaining inner freedom from its incessant pull.

According to an intriguing analysis provided in one passage, the search for satisfaction through a partner is intrinsically related to one's own identification with the characteristics and behavior of one's own gender (Morris and Hardy 1885–1900, IV, 57). In other words, to search for union externally implies that one is still caught up in the particulars of one's own gender role and identity.

Methods for going beyond sensual desire are thus a diminishing of one's sense of identification with external aspects of one's gendered behavior and a sober appreciation of the nature of the body as something whose beauty is only skin-deep. Moreover, developing an inner sense of peace and joy will counter one's tendency to search for happiness outside.

In the case of ill will, patience needs to be developed, ideally coupled with a closer examination of what tends to arouse one's ill will. Here, too, the sense of identity often plays a considerable role in stimulating anger and ill will. An important remedy for overcoming ill

will, mentioned frequently in Buddhist texts, is the development of loving kindness (Sanskrit *maitrī*, Pāli *mettā*), an attitude of friendliness and companionship extended impartially toward all living beings, without making any distinctions or exceptions.

Sloth appears to stand predominantly for mental boredom and lack of inspiration, whereas torpor would correspond to physical lethargy, such as may manifest after overeating, oversleeping, etc. Besides the self-evident need to avoid overeating, oversleeping, etc., a remedy to sloth and torpor could be found in making an effort and in developing clarity of the mind.

Restlessness may arise because of excessive striving and a pushy attitude, whereas worry is usually related to concern with something not done properly in the past or something still to be done in the future. In both cases, calming and tranquilizing the mind will help remedy the situation, together with focusing on the present moment instead of getting lost in the past or in the future.

Doubt as a hindrance is mainly due to lacking a clear understanding of the difference between what is wholesome or skilful and what is unwholesome or not skilful. To overcome doubt, introspective analysis helps discerning the skilful from its opposite. This takes place in particular through investigation of phenomena, the second of the seven so-called factors of awakening, *bojjhaṅga*.

These factors of awakening present a set of mental qualities diametrically opposed to the hindrances, being of particular relevance to progress to awakening. The first factor in this set is mindfulness, followed by investigation of phenomena, energy, joy, tranquility, concentration, and equanimity. Overcoming the five hindrances and developing the seven factors of awakening, then, could be considered the heart of Buddhist meditation practice.

[Anthropology in Hinduism](#)

Description

Interwoven in his creation, the Spirit (ātman or puruṣa) is beyond destruction. No one can bring to an end the Spirit which is everlasting. For beyond time he (ātman or puruṣa) dwells in these bodies, though these bodies have an end in their time; but he remains immeasurable, immortal (The Bhagavad Gītā, 2, 17–18)

This quote refers to the Hindu philosophical understanding of Man as a compound of two elements: (1) the eternal element either called ātman or puruṣa and (2) the mortal element consisting of matter or nature often referred to as prakṛiti. The latter is something you should not strive for, idolize or worship, because that will carry you away from the process of realization. Instead, it is important to ignore its ongoing call

for needs and instead concentrate on what really matters: the understanding of ātman as identical with brahman, the absolute, one supreme, all-pervading Spirit. This realization leads you to moksha, the liberation of rebirths (saṃsāra) and all that binds you to the profane life. Yoga is seen as a method of both realizing the ātman-brahman identity and restraining the bodily needs or mentally disorders coming from the senses, but it also outlines an anthropology, where the ideal seems to be asceticism and a world and life denial ethics. This outlined anthropology is developed in the Upanishads from around 600–300 B.C.E. and further elaborated in different Hindu philosophical schools called the Darśhanas.

But the development of a special Hindu anthropology is an ongoing process modified to the new circumstances, and in later texts, we also find an explicit emphasis on the worldly life as well. Here, the primary goal (moksha) is woven into a worldly committed ethics which could be called “one thing at the right time and place ethics.” This has a strong impact on the understanding of Man because, first of all, it emphasizes that the goal or ethics (dharma) of life depends on varnāśramadharma, the social class (varṇa) you belong to and your stage of life, implicitly also your sex. Secondly, it underlines the importance of human existence as such.

The Hindi poet Tulsidas (c. 1532–1623) rewrote the Sanskrit text Rāmāyana to Hindi in the sixteenth century and gave the text the name Rāmācharitamānas. It is today one of the most influential texts in popular Hinduism, especially in North India, and the following quotation gives an example of how the understanding of the human is seen as a necessary stepping stone for attaining moksha:

It is a great and good fortune that you have secured a human body, which – as all the scriptures declare – is difficult even for heavenly beings to attain. It is a tabernacle suitable for spiritual discipline and the gateway to liberation (Rāmācharitamānas, pp. 720–21)

This means that, while the Hindu tradition upholds liberation (moksha) as the ultimate goal, it also underlines that human existence is the only gateway. But only if you follow the specific

dharma in relation to varna and āśrama – which can be called a relativistic dharma.

Four Goals of Life

The relativistic dharma mentions four goals of life or ends, which can be seen as necessary steps toward the ultimate one. They are meant to cultivate the mind in relation to the position you have in the world according to your stage of life (āśrama), but they are also meant to legitimize worldly needs and strives and, in doing so, to underline the need for engaging in the world before turning the back to the world. The four goals or ends are called *purusārtha* and are as follows: *kāma* (pleasure), *artha* (wealth or worldly success), *dharma* (ethic, right conduct), and *moksha* (liberation from *samsāra*).

In a person's first stage of life as *brahmacārin* (student), the primary goal is to get to an understanding that dharma is the fundamental guideline for your life and that dharma has both a universal expression as well as a relativistic one. It can be called an introduction to the core of the Hindu tradition.

The next stage of life as *gṛhastha* (male householder) or *gṛhīni* (woman householder) in the *dharmaśāstra* literature is seen as the most important stage of life because the other stages of life are depending on it. To fulfill this stage of life, it is necessary to be engaged in the world: get children, work hard, socialize, and so forth. And it is in this stage of life that *kāma* and *artha* are seen as primary goals. The Hindu recognition of *kāma* and *artha* as valid human pursuit tells strongly against the common characterization of Hinduism being life negating. It is true that Hinduism does not uphold these two goals as the highest goals – and they should always be strived for in the light of conducting dharma – but the goals at least approve fulfilling some bodily pleasures and a strive for wealth. The latter is implementing a strong working ethics, which can be seen among Hindus all over the world.

In the last two stages of life as *vanaprastha* (a forest dweller) and as *samnyāsin* (ascetic), the

primary goal is *moksha*. But to gain this goal, the Hindu tradition underlines that it is necessary to have been living through the other stages of life with other ideals of life. In other words, you cannot leave the desire for fulfilling your pleasures, and the desire for achieving material gains before you know the limits of these goals:

Not by non performance of actions does a man attain freedom from action, nor by mere renunciation of actions does he attain the spiritual goal (Bhagavad Gītā, 3, 4)

The Unclean Body

As an overall framework, the Hindu tradition sees the human as a microcosmos containing all the elements and processes of which macrocosmos or the Universe is constituted, including the transcendent or divine entity. This leads to a categorization of the body as consisting of two different substances: matter and spirit. While spirit is the everlasting and clean part, matter is the ever changing and unclean part. To cultivate spirit, it is important to cultivate the matter as well. That can be done by rituals through which the unclean substances of matter are purified or by isolating a person or persons in impure periods (menstruation, death in the family, childbirth).

Yoga can be seen as a thoroughly thought out method of cultivating the body or isolating the two substances of the body. The method or methods that are pointed out include bodily positions, hand gestures, the understanding of the subtle body, and breath control.

contexts, however, are used somewhat interchangeably, and cytology in medical terminology is also used to refer to cells used in pathology which can be easily removed from the body for microscopic examination such as vaginal or oral scrapings. Most of the earlier work in histology and cytology focused on describing structure, but these disciplines are increasingly integrated with genetic, biochemical, and molecular studies on cells and tissues. The “cell theory” is the major generalization in this area and holds that “all living things are made up of cells and the products of cells.”

Self-identification

Science

These disciplines unashamedly identify as sciences with their emphasis on empirical observations of cells and tissues.

Characteristics

Histology and cytology are distinguished by the emphasis on the microscopic structure of cells and tissues.

Relevance to Science and Religion

These disciplines are not generally interested in the study of “science and religion” scholarly or otherwise, although some practitioners of the disciplines may be and may seek to find “god” in the amazingly detailed structure of cells as seen in the microscope.

Sources of Authority

Repeatable and verifiable observations are the cornerstone of histology and cytology, and such data are published in peer-reviewed journals and are summarized in numerous student texts for science and medical students.

Histology, Cytology

School of Medical Sciences, The University of
Sydney, Sydney, NSW, Australia

Related Terms

[Cells; Tissues](#)

Description

Histology and cytology seek to describe especially the structure of the tissues (histology) and cells (cytology) of animals and plants especially at the microscopic level. Technically, histology (Greek, *histos* = woven fabric = tissue) is the study of the macrocellular arrays of cells which make up animal and plant tissues, and cytology (Greek, *kutos* – *cytos* = receptacle = cell) refers to the study of cells. The two terms in some

Ethical Principles

As with most branches of science, the ethical principle underlying these disciplines is full reporting of observations and methods in anticipation that others can reproduce and thereby corroborate them.

Key Values

Curiosity, betterment of the human condition, detailed observation.

Conceptualization

Nature/World

Physical matter and the energy needed to keep it organized.

Human Being

A member of the species *Homo sapiens*.

Life and Death

The “cell theory” holds that “all living things are made up of cells and the products of cells.” Life is a product of preorganic evolution plus organic evolution and natural selection. All present life arises from preexisting life by cell division, and life consists of metabolism, homeostasis, and reproduction. Death is the irreversible cessation of these functions in the individual organism.

Reality

Not specifically dealt with as such but consistent with other science – empirical, reproducible observations

Knowledge

Nature of knowledge not specifically dealt with but only empirical observations are considered “real.”

Truth

Empirically derived knowledge is our best approximation to truth.

Perception

Is the conscious sensation the physical senses produce. In histology and cytology in particular, there is an awareness that what is seen in microscopic images may only imperfectly correspond to the living entity, so our perceptions may be incomplete in this sense.

Time

Not dealt with as such but consistent with scientific world view.

Consciousness

An “emergent” property of the human brain arising from neural complexity.

Rationality/Reason

Our key tool in understanding the physical world and manipulating it to our own ends. Adherence to rules of evidence, objective reporting, and conclusions supported by evidence.

Mystery

Not a useful concept in dealing with cells and tissues. This word may be used loosely to describe something presently unknown, but there is an assumption that if it is part of the physical world, it can be known and eventually will be. If it is unknowable, it is not relevant to science and is probably fantasy as well.

Relevant Themes

Histologists and cytologists are centrally interested in microscopes and microscopy both at the light and electron levels since these instruments produce much of the data we have about cellular structure and function. Frequently in the past, the hand of God has been seen in these images, but this is increasingly a “god of the gaps.” As with much of science, our increasing understanding of cellular function and capacity to manipulate to our own ends (genetic engineering, stem cell technology) brings ethical concerns and concerns that we are “playing god for some people.”

Historical Theology

Gaetano Iaia

Seminario Permanente di Studi Storico-Filosofici
“Pasquale Orlando”, Pontificia Facoltà Teologica
dell'Italia Meridionale, sez. “S. Tommaso
d'Aquino”, Napoli, Italy

Description

Christianity cannot but refer to the event giving rise to its history, the coming of Christ in the world. In the light of the biblical view of history – that assigns even a revelatory value and meaning at the time, the reinterpretation of this event allows us to consider the whole human story, since that moment, as Christian time.

Historical Theology (HT) focuses its interests on the theological doctrines and their developments over the centuries as an outcome of both the biblical interpretation and the consolidation of the ecclesiastical tradition. In other words, following the history of the Christian thought, the HT is mainly interested in the history of the *making* of speculative theology. Studying theological issues, HT takes into account social, historical, and cultural ideas and contexts in which they arose in space and time; as far as possible, it looks for a pure objective review (Hart 2000).

Hence, HT is epistemologically different from the *History of Theology*, which is concerned with

the historical development of theology and analyzes the most significant movements and personalities marking the history of Christian thought and orienting it toward a specific direction. This is a valuable approach but, critically speaking, merely defines (or tell) a story, leaving theological issues open.

HT is also different from the *Theology of History* which, according to a definition by W. Kasper, is rather a reflection on the *structures* of Salvation history and their historical and theological consequences (Kasper 1964). Then, its aim is to develop deeper theological understanding of History. In this way, theological statements are used as criteria for assessing *what has happened*.

Focusing on *Theology in History*, HT is the only theological discipline that, by nature, considers the history as a *theological history*, that is, a *locus* where the understanding of the faith in the diversity of the *thought-forms* of its ages is processed (Lafont 1994). It does not describe nor analyze the past *as past* but, remaining in the present, it allows the scholar to approach customs and modes of thought in some cases foreign or completely far away from his own context. It is a discipline that keeps memory alive, recalling the tradition and its parts, sometimes still valuable in our contemporary era but too often forgotten.

At least as currently understood, HT finds its origin in the late nineteenth century, within German theological (Protestant) Schools; its final development and dissemination took place thanks to the French and German Catholic Schools of Theology in early twentieth century.

Protestant thought aroused considerable debates, especially around both the meaning of the *authenticity* of Christianity and the bond between modern Churches and the primeval Christian community. Important consequences of these debates were both the gradual acquisition of an *historical consciousness* and a clearer and clearer understanding of Patristic doctrines, and their supposed alteration in the Middle Ages. During the nineteenth century, especially in Germany, HT research area enjoyed further developments thanks to the exegetical schools, interested in the *History of the Dogma*.

Affirming that the doctrinal formulations were also a result of social and cultural conditions, these Schools stated that a survey done in accordance with the criteria of historical analysis allowed to consider these doctrinal formulations as inappropriate to the changed conditions of the Church in modern times. Therefore, the Church had basically the task of reformulating these doctrines in order to make them more understandable.

Originally established by G. S. Steinbart, these ideas were received in the writings of F. C. Baur, the founder of the Protestant exegetical School of Tübingen. Influenced by the ideas of Schleiermacher and Hegel, in his book *Die Lehre von der christliche Dreieinigkeit Menschwerdung Gottes und Entwicklung in Ihrer geschichtlichen* he established a new standard for the study of the history of Christian doctrine. After him, the ideas of Steinbart reach their maturity in Adolf von Harnack, and, especially, in his *The History of Dogma*. Von Harnack stated that the dogma, considered *in se*, was not a genuine Christian concept, but derived from the progressive move (or detachment) of Christianity from a Palestinian and Jewish environment to an Hellenistic – especially Alexandrian – one. In order to articulate the transmission of both the faith and the Gospel, in practice Christian writers absorbed the Hellenistic outlook, especially in its dialectical and metaphysical aspects. This concept led von Harnack to assert that even the doctrine of the Incarnation as a result of the Hellenistic influence should be refused, taking, on the contrary, in greater account the *historical* Jesus and the impact that both his action and his preaching had on a specific, chronologically and geographically circumscribed, portion of humanity. The removal of metaphysics from theology, he said, may produce nothing else than a greater awareness of the soteriological aspects already present in the historical life of Jesus (Gonzalez 1987).

Although this view was later questioned, its general methodological principles can still be considered valid for the approach of HT, since many aspects of the Christian faith were influenced by the Hellenistic metaphysics which must necessarily be taken into account for a more serene and complete analysis of the doctrine's

development. It must be recognized that von Harnack highlighted a fundamental element for the subsequent development of HT: History provides methods and tools useful for a better understanding of the theological thought, allowing to define the HT as a *critical consciousness* of theology.

In the Catholic area, one of the main authors of the Tübingen School was J. A. Möhler, who considered theology as a science of an external and historical reality animated by an inner principle. He explained his method and his ideas in an analytical way in the *Symbolik*, published in 1832, which generated many debates (particularly with Baur). For Möhler, HT's primary tasks are the analysis and the re-understanding of the theological tradition not as a representation of the past (nowadays elapsed and set aside), but as a living reality (Dulles 2005).

Theological ideas of different past ages are not only *past*, but they are part of a tradition that endures and lives in rituals and devotions, in the acts of Councils, in theological discussions. Then HT seeks to shed light not only on tradition – which goes beyond any possible and manifold concrete expression in history – but also on ideas and systems of theological thought, including those which are totally dependent on the *esprit du temps* and are therefore outside the contemporary context.

Beyond more specifically controversial issues, the method, along with its typical approach, is what makes Historical Theology *special*: First of all, in fact, it puts the *life* of the Christian community in the middle, examining it in all its aspects and considering it as a response to what has been received by the Christian community as *presence* and will of God.

While remaining within the boundaries of the Anselmian *fides quaerens intellectum*, it must take into account liturgy and worship, discipline and ethics, ecclesiastical organization, biblical interpretation, and theological thought. The Christian community remained true to his vocation, but his thoughts, however, assumed many forms, also as a result of historical and geographical changes. They were transcribed into the *corpus* of Christian doctrines, transfused in the

theology or *theologies* of the Christian community (or, following schisms, of one or more of its divisions).

Tradition and theology, in turn, found further fixation in dogmatic formalizations, expressions of faith of a portion of Christian people in a given context and promulgated as rules for members of the community. Apparently, the scholar may bring only an analysis of the main current or main formulations and not all the theologies and the doctrines of the Church. Therefore, the HT focuses only on the historical development of Christian doctrine – putting at the center of its attention the living but strict structure of dogma – and its main factors that, on occasions, have promoted new formulations or changes. In this sense, it offers the possibility to formulate a clear *status quaestionis* on events and circumstances that contributed to the major theological themes, helping to identify not only the subject of previous analysis or debate, but also the most significant personalities of various historical periods and their key documents.

In order to consider certain visions with equanimity – even if they are different and sometimes conflicting with each other – and without making any preliminary judgment on them, the efforts of the theologian must link with those of the historian, because in order to shed light on theology and history both the disciplines must operate in synergy. The aim is to provide a correct and vivid description made up, as far as possible, with objectivity, knowing that the *terminus ad quem* can only be defined in accordance with rigid space-time parameters: What happened in a given geographical area and in a given historical period is the edge to which the scholar of HT should strive as far as possible, balancing scientific objectivity with own personal involvement. This feature in some ways is the most difficult to define and maintain: HT is in fact necessarily conditioned by the historical period and the context of the scholar. Consequently, even though the scholar may strive to be objective, he certainly cannot be *neutral*.

It is also for these reasons that HT cannot be said simply *history*; in fact, it does not share its purposes nor it can be limited to the application of

historical investigation's criteria and sources (ecclesiastical, intellectual, political, cultural, or social). Rather, it is a peculiar form of *theology* and therefore it must consider its approach as well as its own hermeneutic method in an *osmotic* exchange with other branches of human knowledge – such as psychology, sociology, philosophy of religion – and with a strict and due attention to biblical studies. Theology is a discipline based and dependent on the Word of God, which is *beyond* any historical process and, for good reason, can judge their degrees of correctness.

For HT scholars, the Christian theology is not a *tabula rasa*, but rather a research area already occupied by traditions. Of these, in some ways, they are only caretakers and (sometimes critical) interpreters; at most, they can reform them or help reviewing them, but cannot supersede them, since freshness and newness are hidden within them, and have yet to be discovered. Therefore, in the light of new scientific discoveries, the approach of HT scholars makes possible continuous reassessment of the Christian thought.

Moreover, it makes human beings aware of origins, causes, continuities, and discontinuities of human events and ideas, relativizing in a right way what previously was seen as absolute. Above all, it is a constant reminder that human beings and their communities are *historical*.

The HT method and approach can be useful for accessing and understanding the science-religion intersection, considering conflicts and interactions arose in the course of time.

Indeed, considering the path of science, from its rise in the medieval West up to the scientific revolution, HT must regard not only major even theological shifts – marked by discoveries such as those by Copernicus, Galileo, and Isaac Newton – and the Catholic and Protestant reactions to them, but also the cultural improvement occurred during the eighteenth and nineteenth century, with the changes in geology, cosmology and biology, as well as the scientific revolutions of the twentieth century, that produced answers and reactions from both mainstream religious groups and newer movements such as evangelicalism and fundamentalism.

Consequently, for a complete and systematic analysis of the various theological positions of the contemporary era, HT must take into account even the theological implications of scientific research while evaluating recent approaches such as environmentalism, social construction, postmodernism, which are at the center of current debates.

Historical analysis, if considered from the point of view of the Christian faith and its theology, let us highlight that there are both an ultimate purpose of the historical process and a vital objective of human life, which all continuities and discontinuities of human experience make reference to.

Christian faith, in fact, cannot accept the *historical relativity* (an idea historically unverifiable but rather philosophical) as the ultimate explanation of human condition. When placed within the theological discipline, historical research is not merely a description and interpretation of the past as past, although it may be valuable. While living in his own present, the scholar of history – and especially the scholar of HT – may highlight practices and ways of thinking nowadays unknown to his contemporaries. The Church, as Hans Küng pointed out some years ago, keeps alive memory of its past but sometimes, unfortunately, loses it. It must be helped to remember the things it forgot (Küng 2000). This is the role of the historian and, more specifically, the role of the scholar of HT. In describing or interpreting ideas and practices, the scholar acts as a memory of a tradition and, as the intellectual revival movement called *nouvelle théologie* – arisen in France after the First World War – reminds us, sometimes can have a leading impact on contemporary theologies. In some cases, like the one just mentioned, a history of tradition helps making judgments about the present, to correct or rejuvenate both theological thought and religious life. Therefore, the scholar of HT must be honest about what happened, presenting evidences emerging from historical facts and not from his own concern about the present era, realizing, finally, that his attempt to be objective is related and certainly not indifferent to the Truth.

Historiography (Classical)

Martin Ebner

Seminar für Exegese des Neuen Testaments
Katholisch-Theologische Fakultät, Westfälische
Wilhelms-Universität Münster, Münster,
Germany

Until recently, historiography has referred simply to the “writing of history,” and is to be distinguished from the modern “science” or “academic study of history” (in German *Geschichtswissenschaft*). Historiography in Greco-Roman

antiquity sought to ascertain the rational causal connections between events of the more distant past and the immediate present by forging them as a narrative. It exposes myth decidedly as fiction. According to Aristotle, the goal of fiction, especially drama, is to articulate what can perennially happen, what are termed “paradigms.” In contrast, historiography accounts for the special, individual case (Aristotle, *Poetics*, 9). Myth explains the processes of nature and the actions of human beings in terms of the influences of the gods. It thinks in cycles of time and originates in those realms that are outside human control. Historiography, however, seeks this-worldly explanations and sees history as the totality of autonomous individual experiences, which are patterned after human design. It thinks in linear time sequences and stems from a technical way of thinking using measurable criteria. Important considerations for the historiographer are the *epos* (which relates the outcome of events), journeys of discovery (which secure the empirically determinable data about geographical areas), and the Ionian philosophy of nature (which looks for rational explanations for incidents in the world of appearances).

Herodotus (ca. 484–424 B.C.E.), the “father of historiography,” set down three goals for the discipline: (1) events should be rescued from oblivion (*memoria*); (2) only important and decisive facts should be chosen (“selection”); and (3) the causes of events, especially wars, should be explicated (“theory”). Thucydides (c.a. 455–400 B.C.E.) introduced the securing of historical data (“autopsy”) as the criterion of truth for historiography. The sites of occurrences must be investigated and the events themselves that are reported must either be experienced, or their eyewitnesses interviewed (Greek *historia*=“witnesses”). The object of this primary investigation includes the different versions of the accounts of eyewitnesses, which compares their subjective experiences as related to their memory capacity with independent reckonings of the same occurrences, as well as to prove their likelihood. The single fictive element in the account given by the historian, according to Thucydides, are speeches.

In them the motives and underlying reasons for history are to be laid bare.

In Hellenistic times, two strands of historiography were set forth: (1) melodramatic historiography, which like fiction or drama portrayed the universal validity of certain basic human situations in their true-life particularities (*mimesis*) and thus might move the reader, or viewer, emotionally; (2) pragmatic historiography, which concentrates quite strictly on the establishment of causal linkages between events. From the beginning onward two ways of selecting material could be distinguished – universal history, which deals with large spans of time and aims to connect the present with cultural and political developments in the past (e.g., Herodotus, Polybius, Livy); treatises or monographs, which illuminate specific events from contemporary history (e.g., Thucydides, *The Peloponessian War*; Sallust, *The Conspiracy of Catiline*).

Reflections concerning one’s own specialty of historiography are to be found here and there, mainly in the prefaces of historical writings (e.g., in Herodotus) as well as in chapters on methodology (e.g., Thucydides, Polybius). From Lucan can be obtained an essay on “how one is supposed to write history,” or how to manage and render materials. Only the modern “science” of history starting in the nineteenth century takes the constructivity of its own historical reconstructions as its theme.

History of Ideas (Intellectual History)

Colbey Emmerson Reid
 Department of English and Humanities, York
 College of Pennsylvania, York, PA, USA

Related Terms

[Intellectual history](#)

Description

History of ideas is the interdisciplinary inquiry into the workings of human thought as it transgresses conventional categorization according to historical period, geography and ethnicity, schools and *-isms*, and the division between high and low culture. Targeting a mixed academic audience rather than specialists in a single field, the historian of ideas rejects the compartmentalization and departmentalization of post-Enlightenment thinking. Instead, the tradition examines synthetic complexes, or “unit ideas,” that may seem superficially dissimilar due to their different expression across philosophical and cultural temperaments but nevertheless possess resonant congruities.

Recent contributions of the history of ideas include the growth of humanities centers in contemporary universities, which extend the tradition’s effort to corral together scholarship in literature, philosophy, religion, foreign languages, the fine arts, and the history and rhetoric of science. The history of ideas has also raised questions about the relevance of periodicity as a substantive marker of textual and conceptual similarities and differences, advocated an approach to “comparative literature” attendant to the international and interlinguistic dialogue of ideas, and interrogated identity-based divisions of texts and cultures that can be better understood in more global contexts. The emphasis among historians of ideas on comparison and synthesis has offered an antidote to postmodern tribalism and its insistence on the logic of cultural difference.

The holistic approach to thought adopted by the history of ideas facilitates treating the methodologies of science and religion not as antithetical but as inextricable from one another, inaugurating a postpositivist approach to science that is deeply critical of the common valorization of empiricism and rationality as the sole viable modes of intellectual inquiry. The intellectual historian assumes instead that human nature and experience is vastly complex and that no element of it can be understood independent of its relations to all other things. The tradition’s

assumption of the impossibility of complete knowledge contrasts sharply with the scientific “man of action” confident in the power of human understanding to produce certainty through empirically verified knowledge.

Thus, the history of ideas proffers a critique of science as it is conventionally constructed, one invested in the discovery not merely of information but of the formative theoretical concepts that shape the gathering and interpretation of information. Prominent religious unit ideas, for instance, can structure systems of thought underlying and even enabling scientific discoveries. Science is thereby treated as an extension of metaphysics and not metaphysics’ opposite. Thus intellectual history is a way of introducing scientific invention to the conditions for its own existence and imagining the new conditions in which future inventiveness might exist.

Intellectual historians have also used scientific practices to critique the humanities, however, as in Franco Moretti’s *Graphs, Maps, Trees: Abstract Models for a Literary History* (2007). Moretti’s study bears mentioning for its assertion that the humanities might profitably adopt scientific methodologies like counting, graphing, and mapping as antidotes to the ubiquity of reading in humanist inquiry. Moretti believes that reading relies upon too limited a body of evidence insofar as it is mainly confined to canonical books and authors and unable to account for multiple texts at once. Graphs, maps, and trees, however, could unveil a mass cultural spectrum of ideas and suggest global continuities scholars are unlikely to see due to the normalizing and exclusionary influence of existing and elite transmissions of knowledge. Within the history of ideas, scientific empiricism can paradoxically be a vehicle of public opinion, an element of collective thought too commonly lost in the humanities’ tendency to focus exclusively upon ideas expressed within a small number of masterpieces composed by a few eminent writers.

The history of ideas takes inspiration from religion no less than science, however, as when it emulates certain practices in comparative religion which trace the structures underlying deeply divergent religious practices and belief

systems, and notes profound variations within presumably monolithic systems. G. B. Vico, sometimes named as an antecedent historian of ideas, wrote of theology as the “new science” of modernity. Vico’s representation of theology was an antidote to Cartesian rationalism in its own era, contending that unifying structures of thought could become apparent through the intercultural study of art, mythology, and rituals. Theology preserved an important component of thinking, one considerate of relationships between ideas, to complement the discrete and particular modes of knowledge accessed through the scientific method.

Vico’s “new science” was antimodern in its insistence upon the continued relevance of theology, but it nevertheless resembles the critique waged from within modernity by numerous thinkers who have questioned the value of many of modernity’s conditions. For instance, Nietzsche’s theorized poetry as the “gay science” of experiences that exceed the limiting mediocrity of the rational. Claude Levi-Strauss’s structural anthropology took seriously the persistence of transcendent cultural forms. And Foucault relied upon the spiritual art of revelation as an antidote to the soul-deadening construction of selfhood orchestrated by institutional power. In each case, mystery or “spirit” is not that which must be overcome to pursue ideas but that which must be recovered to facilitate a more authentic and contextualized intellectual culture.

The distinctiveness of the history of ideas thus pertains to its insistence upon the relevance of metaphysics and aesthetics to the modern pursuit of knowledge. Rather than trying to eliminate the ambiguities of affective modes of perception, the historian of ideas studies the meanings, associations, and even obscurities therein suggested. One of the unique key values of the tradition is error, insofar as the historian of ideas is interested in human thought even when it is confused or absurd. Another key value can be found in the persistent defense of universalism, in that the history of ideas tends in its active sense for the vast entanglement of ideas with one another to view cultures and people as fundamentally syncretic. Though ethics is not an explicit

component of the tradition, one can extrapolate critiques of nationalism, essentialism, and the institution, which manages thought by penning it within stable categories that limit challenges to the institution's structural integrity.

Sources of authority within the field include Arthur O. Lovejoy's "Introduction to the Study of the History of Ideas" in *The Great Chain of Being* (2007), which theorizes before practicing the tradition in the analysis of a religious unit idea and also coins the terms "history of ideas" and "unit ideas." Lovejoy critiqued pragmatism for importing scientific positivism into the humanities, but the influence of William James, who was Lovejoy's teacher, in his pupil's invention of the history of ideas can be discerned in James's "A World of Pure Experience" (1904), which theorizes a *Weltanschauung*, or unified world, that can be recovered through "radical empiricism," the registry even of the transitions and conjunctions between ideas as important components of experience. On science and religion, important texts include G. B. Vico's *New Science* (2002), especially accompanied by Mark Lilla's *G. B. Vico: The Making of an Anti-Modern* (1994). Also see Jeremy Carrette's edited selections on *Religion and Culture: Michel Foucault and Foucault's "Nietzsche, Genealogy, History."* Important recent contributions include Mieke Bal's *Travelling Concepts in the Humanities* (2002), Franco Moretti's *Graphs, Maps, Trees* (2007), and Carlo Ginzburg's "Minutiae, Close-Up, Microanalysis" (2007), which discusses the importance of the "microanalysis" of historical minutiae in uncovering significant "macroconcepts" otherwise lost to historians. Ross Posnock's *Color and Culture: Black Writers and the Making of the Modern Intellectual* (2000) brings the history of ideas into critical contact with identity politics. Finally, Susan Sontag's *Against Interpretation and Other Essays* (1994) explains how art and literary criticism might better attend to intuition and affect in their readings of texts, and her essay, "Fascinating Fascism" (2002), models the intellectual historian's attentiveness to conceptual unities in its analysis of extant and thriving fascist unit ideas in western constructions of beauty.

Lovejoy, who founded the "History of Ideas Club" at Johns Hopkins University in 1940, is the most immediate source of the terminology and theory of the history of ideas. Nevertheless, within continental philosophy, Nietzschean "genealogy," Foucauldian "archaeology," and Derridean "etymology" all similarly destabilize the natural appearance of conceptual commonplaces by tracing their invention and evolution.

The history of ideas conceptualizes *the world* as structurally connected by the limited diversity of ideas across cultures. *Nature, reality, knowledge, and truth* are perpetually reconstructed by the individual perceiving them, thus placing the *human being and human consciousness* at the center of the tradition. Notions of the *origins of life and the function of death* are not relevant to the history of ideas, except insofar as they might serve as unit ideas. *Time* is rejected as a valid marker of unity or difference, as the historian of ideas might find profound variation within chronologically simultaneous ideas while tracing the continuity of other ideas over centuries. The history of ideas should be understood as a critique of the modern ascent of *rationality* as the ultimate value and insists upon permitting the reemergence of *mystery* as an essential component of thinking through engagement with theology and art.

[Medical history](#); [Restoring health](#)

Description

Medicine may be defined as the art of preserving or restoring health and treating disease, illness, or physical dysfunction by means of drugs, surgical procedures, or manipulations. The history of medicine is the history of both the changing concepts of health and disease and the greatly varied social roles and ethical responsibilities of those who seek to preserve or restore health. The former is properly an aspect of the history of science in general and of the biological sciences in

particular. The impact of religion on the history of science, in its broadest sense as well as in some of its specific disciplines, is reflected in the history of changing concepts of health and disease. The roles and responsibilities of medical practitioners, while affected by changing scientific concepts, are less features of the history of science than of social, religious, moral, legal, and economic history.

Self-identification

The study of the history of medicine in America owes its beginnings not to professional historians but to physicians, who were in many cases men of broad culture and classical education. In the first half of the twentieth century, American medical schools produced a distinguished group of physicians, like the neurosurgeon Harvey Cushing (1869–1939), who were not only enthusiastic students of the history of medicine but who published in the field. It would be unfair to call them (as they have been termed) amateurs. But they were clinical specialists, not professionally trained historians. Most prominent was Cushing's mentor, William Osler (1849–1919), one of the four founding members, in 1893, of the School of Medicine at Johns Hopkins University. Osler believed that the study of medical history, of great doctors, of the history of disease and therapy, and of the classics of medical literature from Hippocrates to the present would illuminate modern medicine by placing it within its broader cultural context. But more than that, he believed that it had the potential for humanizing medicine and for maintaining the proper balance between the art and science of medicine. Osler incorporated the history of medicine into the clinical courses that he taught rather than treated it as a separate subject for study. In the first half of the twentieth century, courses in medical history expanded in American medical schools, reaching their peak in the 1950s, then declining rapidly. In the 1970s, the newly emerging field of bioethics brought to the public consciousness a whole series of urgent questions. Like many new disciplines, it quickly expanded, producing new

journals, departments, and symposia. Courses in medical ethics began to proliferate in American medical schools, replacing courses in the history of medicine. Paradoxically, during the same period that the history of medicine was being dropped from the curriculum of medical schools, courses in medical history were proliferating in history departments at many universities. But their approach was very different from that adopted in medical schools. They taught the social history of medicine primarily to undergraduate or graduate students in history (Burns 2000).

Characteristics

Scores of universities today offer courses in the history of medicine. They are nearly always taught by professionally trained historians with Ph.D.s rather than M.D.s, and their approach is sociological. Some departments of medical humanities in schools of medicine now hire professionally trained historians to teach medical history as well, with the result that new historiographical methods are penetrating medical schools. As a specialized field of historical research, history of medicine in the United States is quite healthy today, but as a field of history, not of medicine. It has, like the history of science, come under the strong influence of *social constructionism* and Kuhnian ideas of the *sociology of knowledge*. This professionalization has itself been partially responsible for the decline of the teaching of medical history in schools of medicine. And it has widened the gap between physicians who teach medical history and academically trained historians. By applying the methods of cultural studies to medicine and by placing it within the context of the new social history, historians have rendered the subject more naturally suited to departments of history than to medical schools.

Relevance to Science and Religion

In the past generation, historical scholarship has devoted a good deal of attention to the

relationship between science and religion. Two historiographical perspectives that have influenced, even revolutionized, scholarship provide the orientation of the discussion. The first is the reaction against what is commonly called *Whigism*. The term denotes a perspective that views the past through the lens of the present and sees history as moving progressively toward the ideas and institutions of a later age, particularly one's own. Many historians of medicine writing today attempt to avoid its correlatives, presentist and essentialist approaches, which have traditionally influenced the historical understanding of both religion and science. *Presentism* is the tendency to shape the past by employing modern definitions and understandings. *Essentialism* assumes that an idea or a discipline is basically the same in all ages and that the history of medicine is distorted by imposing modern definitions on the study of the past or by admitting as truly scientific only what a modern medical scientist would regard as such. *Social constructionism* provides the second modern perspective that informs much recent writing in the history of medicine. Social constructionism is a methodological orientation that views the pursuit of scientific knowledge not as an autonomous but as a human endeavor that reflects social backgrounds and conditions as well as the prevailing spirit of the age. It marks a reaction to the previous dominance of *positivism* in the history of medicine (Ferngren 2002: ix–xiv).

Sources of Authority

Social constructionism as an intellectual movement was inspired by Thomas Kuhn's *The Structure of Scientific Revolutions* (1962), which accounted for major transformations in science (Kuhn termed them "paradigm shifts") as the result of social and psychological factors. Kuhn's approach owed much to antirationalistic and relativistic notions and marked a reaction to the long-standing emphasis on the autonomy and rationality of traditional science. It unintentionally created an agenda for the next generation of scholars, who pursued what came

to be called *science studies*. Their research program emphasized the *sociology of knowledge* and the contextual and socialcultural setting in which new science developed. Positivistic scientists and intellectual historians of science and medicine reacted vigorously in defense of older views, however, and the resulting “science wars” came to characterize the last two decades of the twentieth century. Adding to the ferment was the emergence of feminism and postmodernism. Feminism became a major force in the scholarship of many academic disciplines, including history of medicine, with its study of gender as a factor in the construction of medical knowledge and its exploration of women’s participation in medicine.

Another major factor has been the rejection of the thesis formulated by John William Draper (1874) and Andrew Dickson White (1896) that Christianity has had a long history of opposing scientific progress. White, the first president of Cornell University, argued that the early church had hindered the progress of science both by denigrating the investigation of nature and by subordinating observation and reasoning to the authority of scripture and theology. The Draper-White or “conflict” thesis, as it is called, became enormously influential in America in both popular and academic circles. During much of the twentieth century, it dominated the historical interpretation of the relation of religion and science (Lindberg and Numbers 1986: 1–18). In the late twentieth century, the thesis underwent a systematic reevaluation. The result has been the growing recognition among historians of science and medicine that relations between religion and science have been much more positive than is often thought. John Brooke suggests that a “complexity thesis” is a more accurate model than the familiar conflict thesis (Brooke 1991). Although popular images of controversy continue to exemplify the supposed hostility of Christianity to new scientific and medical theories, recent studies have shown that Christianity has often nurtured and encouraged scientific and medical endeavor, while at other times, the two have coexisted without either tension or attempts at harmonization. If Galileo and the Scopes trial come to mind as examples of conflict, they were

exceptions rather than the rule. Christian clergymen, for example, actively supported the introduction of inoculation and anesthesia.

Ethical Principles

Postmodernism has injected a radical, though hardly pervasive, influence in the modern study of medical history. Postmodernists reject all “totalizing” systems, arguing that no human endeavor, not even medicine, can claim to be based on universal truths or on Enlightenment-based assumptions, such as rationality. Hence, they deny the universal claims of both medicine and religion, which have found themselves deprivileged and attacked for their authoritarian pretensions (Ferngren 2002: 381–387). Assumptions of cultural and ethical relativism are widespread in the modern social history of medicine. But recognition that medicine and religion have developed historically and have been influenced by their historical and cultural context does not necessitate acceptance of relativistic assumptions. Nor need it deny the claims of Christianity or other religions to special (i.e., divine) revelation. It does, however, require an awareness of the cultural limitations that are imposed on all societies, ideas, and disciplines, including our own. And it should persistently strive to avoid the comfortable assumption that modern Western cultural values or current theoretical constructs constitute the bar before which all other values are to be judged. The modern age is a historical period like any other, limited in its perspectives by time and culture, and subject to the constraints of its own zeitgeist. Understanding that we, too, have historical limitations should force us to view the past in a manner that is neither patronizing nor disparaging, but appreciative of the power of ideas and practices that we do not always share or fully understand.

Key Values

Every language employs a variety of words, some precise and some imprecise, to express the

manifestations of physical disability and dysfunction. When imprecise terms are used to indicate that someone is ill, the language is usually not scientific and does not denote a particular medical condition. One often employs general terms to express merely the perception that one is not (in the commonly accepted understanding of the term) in good health. Hence, words like *illness* and *sickness* carry with them a social or cultural rather than a scientific medical connotation. Among medical anthropologists, *disease* is usually taken to describe a pathological condition, while *illness* denotes a subjective feeling of physical discomfort. But even when a specific (i.e., medical) vocabulary is employed, if it is symptomatic rather than pathological, it normally reflects the particular culture that created it rather than indicates a scientific description. And when the vocabulary of disease becomes pathologically specific, it reflects a particular classification of disease or medical model that is culture-specific and cannot be taken as necessarily consistent with modern theories of disease (Kleinman 1980: 72).

Conceptualization

Given the emphasis in the current study of the history of medicine on *contextualism* over earlier traditions that shared assumptions of essentialism and presentism, it is impossible today to provide precise definitions of key terms in the history of medicine. Indeed, contemporary writing in the field tends to avoid general definitions in favor of carefully nuanced and temporally conditioned conceptualizations. An example is the variety of definitions of health that have been given at different times and in different cultures. *Health* is an imprecise concept. The words for *health* in many languages are semantically related to ideas of wholeness and are virtually synonymous with wellness and even well-being. They may refer to the body, the mind, and the soul. The World Health Organization has defined health as a “state of complete physical, mental, and social well-being, and not merely the absence of disease or infirmity.” Metaphorical uses of health are virtually limitless. The basic definition of the

concept is the absence of disease. The spectrum of disease includes sickness, infirmity, illness, mild physical discomfort, dysfunction, disability, and deformity. *Disease*, like *health*, can be used metaphorically and applied to body, mind, and soul.

Relevant Themes

Posing questions to sources that are separated from the modern interpreter by a considerable spatiotemporal as well as cultural and imaginative distance is a familiar problem to the scholar who seeks to interpret historical texts. In the study of the historical relationship of medicine and religion, several issues are relevant for the modern student who wishes to adopt a balanced approach to understanding the evidence. (1) Though recent scholarship has rendered untenable the Draper-White (conflict) thesis, it continues to underlie some modern studies of the historical relationship of medicine and religion. Yet it reflects a dated positivist outlook, viewing biomedicine as continually progressing and overcoming the entrenched antagonism of religious opinions, which invariably retreat before its advance. That view is simplistic and will not stand close examination of the context in which the supposed conflict arose. (2) Many modern historians who have adopted the theories and models of the social sciences, such as social anthropology, view theological or ideological factors in history as mere epiphenomena, choosing to employ cultural or material explanations of a sociological nature. While the insights of the social sciences can be helpful, they provide pitfalls as well as benefits. Ideologically laden with Western cultural assumptions, as they are, the methods of social anthropology need to be used to complement – not to replace – the textual-philological historical method. A synthetic approach, which assumes a mutual interaction in which ideas contribute to the shaping of cultural and social phenomena, just as cultural and social phenomena contribute to the shaping of ideas, provides greater balance (see Ferngren 2009: 8). (3) The past several decades have seen the rise of

poststructural and postmodernist theories, which reflect the influence of French scholars such as Roland Barthes, Jacques Derrida, and Michel Foucault. Poststructuralists argue that discourse reflects no reality other than its own and cannot be taken as an accurate portrayal of the events (“pretextual reality”) it describes. Truth is not discovered but made, historical events not reconstructed but constructed. The meaning of any ancient text is not to be found in the author’s world of thought, but rather in the interpreter’s own world, where, appropriately deconstructed, it can be constructed in a manner that is free from the controlling function of the cultural or literary world that gave rise to it. The notion of history as a process of cause and effect receives short shrift in a historical quest that focuses on modes of discourse as the nearest one can come to “real historical processes” or “extralinguistic realities (Ferngren 2009: 8–9).” For a critique, (see Strenski 1998).

Holism

Silvana Procacci

Department of Philosophy, Faculty of Letters and Philosophy, University of Perugia, Perugia, Italy

Related Terms

[Whole](#)

Description

The term “holism” derived from the Greek “*hōlon*,” “whole,” and designed the doctrine of global interconnection and dependence. Holism focuses on two notions: the first is that wholeness “is more than the sum of its parts” and the second is that if “these parts are taken to pieces, the more the phenomenon is complex, the more the information and the knowledge about it are lost”.

A whole is not simple but is an organic unity in which the parts cooperate in the function for the stability of the system. A whole is *more* than the sum of its parts, i.e., demonstrates an inner relation among the parts and a degree of information of the system particularly important in the case of the complex phenomena. On the contrary, the mechanical approach obtains its major results only analyzing the parts, and doing this loses that *more*. In this way, the whole is not something additional to the parts: it is *these* parts but so *strictly interconnected* that the characteristics and the activities of them are *changed by the synthesis*. In this respect a whole possesses an autonomous power of causation, regulation, and correlation: *it forms a system qualitatively different from the sum of the parts*.

During the first years of the twentieth century, the erosion of the classical analytic and reductionistic paradigm opened from the epistemological side, favored the discussion about the opportunity to study nature – in particular the living phenomena – with a global, or holistic, approach. Many philosophers and scientists, especially in the field of biology, considered the following problems:

1. To affirm the independence and autonomy of biological science in comparison with physical and chemical sciences.
2. To show the limits of the method of analysis to study a complex phenomenon – i.e., a living organism – and to discuss the applicability of a global or holistic method to nature.
3. To explain the marvelous and incessant increasing toward complexity showed by natural phenomena, from inorganic to organic, from matter to mind, and from individual to social, as the result of a natural principle, as a tendency in the universe to form wholeness more and more complex.
4. To develop a philosophy of the interconnection of all the parts with the whole and a vision of nature as a big organism able to self-organizing and self-evolving.
5. To overpass the metaphysical division and the incommunicability between natural science and human science, matter and spirit, inorganic and organic, and naturalism and spiritualism. In this sense, holism is seen able to develop a monistic but a nonreductionistic approach and an openness to the spirituality and religiosity. In this perspective, some philosophers conceived the sacred not as a metaphysical construction but as a result of the cultural evolution of humankind, i.e., a constitutive tendency of reality toward an increasing of hierarchical levels toward complexity.

During the second half of the twentieth century, the holistic vision is near and supported by the science of complex systems. The systemic paradigm recognizes four principles for explaining reality in its essence (both material and immaterial): *hierarchy*, *emergence*, *communication*, and *control* (Prigogine 1989; von Bertalanffy 1969). Hierarchy is able to explain

reality as a system of systems, whose main characteristics are openness and connectedness. Emergence denotes an evolutionary state of reality which manifests itself as creativity, i.e., the occurrence of novelty (emergence) in its becoming. There are many levels of organization. Each level produces (causes) a kind of reality that cannot be broken down into more basic elements. In conclusion, there is a pluralism of realities and properties, correspondent to regional ontologies.

Communication, or transmission of information, is the principle that confirms the ontological need of connecting components in the unity of system. Control is the principle that set constraints by a system against its subsystem components.

The general framework for explaining reality according to a system paradigm is to represent it as an unfolding, evolutionary, self-organizing universe. Reality appears as a continuing development process characterized by a series of nested levels of organization of increasing complexity and autonomy. Autonomy manifests itself as the capacity to last in a state of dissipative structure governed by an autopoietic regime.

The origin of the debate on the relation between the whole and the parts is obviously immemorial, but the notoriety of holism is due to General J. C. Smuts – a South African statesman, Prime Minister of South Africa, soldier, scholar, and philosopher – who published in 1926 *Holism and Evolution*, a book that concerned the debatable borderland between science, philosophy and religion (Procacci 2001, 2003; Smuts 1926).

Smuts created the term holism to distinguish wholes in the strict sense from mere aggregates, mechanical assemblies, and chemical compounds. These kinds of phenomena can be studied analyzing their parts and simplifying the interconnections among the parts as much as possible. In a true whole, the parts lose their prior identity, while in aggregates, the identity of the parts of elements is not lost but is always recoverable. He conceived reality as a hierarchical level of complexity: at the bottom of the ladder, mechanistic features and the ontology of the part predominate, while at the top, there are holistic features.

Wholes are exemplified in minds or psychic structures, which appear among higher organisms, in particular in the human personality, that is considered by Smuts the supreme embodiment of holism, but even atoms and molecules are wholes, but much simpler. In the sphere of spiritual values the holistic process in nature shows its clearest importance.

Smuts refused the division among matter, life, and mind, while suggested a genetic interrelation and rise with each other throughout the course of natural evolution. So, life is developed from matter, and mind has an evident physical basis. But from this thesis is illegitimate to infer, like the materialists do, the primacy and self-sufficiency of matter and to reduce life and mind to a subsidiary and subordinate position as mere epiphenomena of the unique reality, matter.

This erroneous and reductionistic viewpoint derived from the influence of the hard physical concept of cause and effect, elaborated in the science of the nineteenth century, that sustains there could be nothing more in the effect than there was already in the cause; and if matter caused the soul, there could be nothing more in the soul than there always was in the matter. In this respect, the spiritual phenomena were considered merely appearances and not a real advance on matter, and at the same time, the complex systems were obscured to privilege the elementary and the simple.

For this reason, the evolutionary theory, assured as a metaphysical-philosophical interpretation of nature, is for long time considered as the origin of the opposition between materialistic and spiritualistic. On the contrary, conceiving nature as an evolution of wholeness and complexity, we can overlap a universe as a purely physical mechanism to award importance to the psychical and spiritual causes.

The atom, the cell, and the mind are the great fundamental structures of the holistic universe. In particular, the mind is a continuation of the simple and linear behavior of the inorganic level and of the capacity of self-organization of the organic level. The conscious acts are the emergence of a complex level of organization of the matter. From a biological point of view, human

personality is a new synthetic system in which the material and the psychical elements are incorporated in a new complex whole. The mind is able to coordinate all the experiences and is an instrument of individuality and of socialization through the language and the abstraction faculty. But the major character of the mind is its partial freedom from external determination. In fact, while the inorganic is approximately governed by deterministic constraints and animal is conditioned by its hereditary characters, the human personality is oriented by the cultural evolution and social environment. The mind is so a new system of organic regulation and interrelation with the world.

The holistic vision considers wholes not mere artificial constructions of human thought, an epistemic results of the human knowledge, but an ontological aspect connected with the evolutionary process of the natural world. Therefore, universe is governed by an intrinsic whole-making or “holistic factor,” and holism is the term coined to describe from a philosophical point of view this tendency to create novelty and organization. Every natural element, even an atom, is a whole, with specific internal organization and self-direction. Holism expresses an evolutionist paradigm. Evolution is properly the progressive development of wholes in different stages, from the inorganic to the most organized phenomena, like the human mind and the social organism.

A critical issue in holism as regards “science and religion” is the notion of personality and subjectivity (Caporali et al. 2008). Subjectivity includes the individual perception of the outside world and the own body as well as the self-consciousness, or experience of the self. The personality is based in the experience of the individuality as a whole capable of reasoning and valencing. Holism is a vision which supports a coevolutionary relational ontology of personhood, an integrated model of the different aspects of reality in which ethical and spiritual values have their role and dignity. Human values are treated as not eliminable causal factors. In this sense, subjective values have objective consequences in the brain. This holism implies an emergent evolution of the human personhood

that is not governed merely from the lower level of the gene but from a purpose, values, and meaning. In this way, it is possible to restore the human dignity, freedom of choice, and the inner creativity against the reductionistic, dualistic, and materialistic approach. For these reasons holistic reflections pertain to the gap between science, philosophy, as well as religion.

[Afterlife](#); [Life after death](#)

Human beings die and their bodies decay. But could it be that humans will still continue to live in some form after death or return to life? There is a widespread belief in a life after death, and all major religions provide their own views on the subject (Obayashi 1991). It has traditionally been thought that the question of life after death cannot be studied by science. However, science has emerged as an important dialogue partner for

religion and philosophy even in this area. Of particular interest for science are people's experiences at the border of life and death.

► [Near-death experiences](#) (NDEs for short) are life-transforming experiences which sometimes occur when a person is near death. NDEs have been the subject of much scientific interest ever since the publication of Raymond Moody's study *Life After Life* in 1975 (Moody 1975). Research has been carried out, for example, to determine the common features of such experiences and whether they can be explained naturalistically (Bailey and Yates 1996; Holden et al. 2009). Near-death experiences typically involve hovering over one's body in immaterial form, traveling through a tunnel, seeing a light, experiencing a sense of peace, meeting deceased persons, and a life review. Research has focused mostly on positive NDEs which leave a feeling of peace and have positive aftereffects, but there are also negative NDEs which include feelings of aloneness and judgment. There have been many attempts at explaining NDEs naturalistically, but this has proven difficult. No positive correlation of NDEs with medication or mental illness has been discovered, and proposed physiological and neurochemical explanations do not account for the details of the experiences or fit the diverse situations in which they occur. Furthermore, there are many intriguing accounts of NDEs that contained accurate information, for example, about doctors' and relatives' behavior from the time the experiencer was clinically dead. Many researchers believe that near-death experiences give at least some reason to hope for life after death (Moreland and Habermas 1998). There have also been studies on, for example, people's deathbed visions (Osis and Erlendur 1997) and cases where people claim to have memories of earlier lives (Stevenson 1980).

The possibility of life after death is dependent on the nature of the human person. Assuming ► [dualism](#) of the mind (soul or spirit) and the body, it seems easy to conceive of life after death. However, if human persons are completely material, many feel that conceiving of survival without a body is more difficult. Even supposing that a completely identical human person were

created later, there does not seem to be anything to bridge the spatiotemporal gap between the body that died and the resurrected body. If this understanding of the problem is correct, then scientific evidence in favor of a materialistic understanding of human persons would also count against the possibility of life after death (Hasker 1999).

As a materialistic account of human persons has gained ground, many hope that in the future science will allow us to prolong our lives indefinitely. Supposing that consciousness can be understood in fully materialistic terms, ► [mind uploading](#) should be theoretically possible. This means uploading one's consciousness into a computer or a mechanical brain to ensure survival. Perhaps in the future, it will also be possible to stop the process of aging and heal all physiological conditions (Kurzweil 2005). Cryonics is the practice of low-temperature preservation of human bodies or at least brains in the hope that just such ways to prolong our lives will be found, as well as some way to bring people out of cryopreservation alive (Ettinger and Tanly 2005). While this possibility still seems very far-fetched, it is an interesting example of the way the hope for life after death is expressed through both religion and science.

Description

The term “Theology of Hope” is associated with Jürgen Moltmann and his book *Theology of Hope*. In this seminal publication, Moltmann defines eschatology as the doctrine of Christian hope “which embraces both the object hoped for and also the hope inspired by it” (Moltmann 1967, p. 16). He no longer wants to confine ► [eschatology](#) to a discourse about the so-called last things which will happen in the end but to consider the whole cause which drives toward this end. This book signalled the change from a static to a dynamic eschatology, from one that waited for the end to one that, inspired by the future promise, attempted to inaugurate some of that hope in the present. During the social unrest of the 1960s, this book spawned a whole movement of theological reflection on social involvement such as *Theology of the World*

(Johannes Baptist Metz 1967), *Theology of Liberation* (Gustavo Gutiérrez 1972), and even a *Theology of Revolution* (late 1960s with various authors). Today, it is widely accepted that the Christian hope is not just otherworldly but has (social and ethical) implications for the present.

Self-identification

Science

Insofar as theology has traditionally been understood to be an academic discipline, theology of hope is an academic discipline too. In the German context out of which the theology of hope originated, one distinguishes between the *Naturwissenschaften* (natural sciences) and the *Geisteswissenschaften* (intellectual sciences). In this way, a theology of hope is part of the intellectual sciences and therefore a science. Moreover, a theology of hope employs exegetical and historical studies which aim at scientific rigor. With regard to its societal implications, one should not forget that precise social analysis is required which again points in a scientific direction. Wolfhart Pannenberg has pointed out in his book *Theology and the Philosophy of Science* that especially in its eschatological direction, theology fulfils the three minimal criteria which Heinrich Scholz has adduced for a discipline to be regarded as scientific: (1) It makes assertions which are regarded to be true, (2) these assertions must be related to the object matter with which this science is concerned, and (3) one must be able to examine the truth-value of these assertions.

Religion

Theology of hope is a theological discipline and therefore is part of the intellectual exercise of the study of the Christian religion. More narrowly defined, the theology of hope is part of systematic theology. It has been promulgated by Christian theologians, especially in Germany, of both Protestant and Roman Catholic persuasion.

Characteristics

Distinctive for the theology of hope is the rediscovery of eschatology as a dynamic category which allows anticipating *proleptically* something of the envisioned goal on account of the resurrection of Jesus Christ. Moltmann distinguishes between the Israelite religion of promise and the static epiphanic religions in the environment of Israel. After the Israelites' conquest of Palestine, Yahweh still appeared as the promising God who pointed to a new future. This meant that the Old Testament promises were never superseded by historic events but were constantly modified and expanded. Of course, some were realized in history. These "fulfilled" promises to which Israel owed its existence (the Exodus, the Promised Land, David's kingship) proved, amid all the upheavals of history to be a *continuum* in which Israel was able to recognize the faithfulness of its God. Yet, the promises were not completely resolved in any event, but there remained an overflow that pointed to the future. Moltmann declared: "The tension between promise and fulfilment was not left behind by the simple progression of Israel's history, but was much more strongly creative of Israel's historic progress" (1967, p. 111).

Moltmann sees the same feature in the New Testament because the revelation in Christ is at the same time good news and promise. This revelation presupposes the law and promise of the Old Testament since Yahweh (the God of Abraham, Isaac, and Jacob, the God of promise) resurrected Jesus and Jesus was a Jew. This is taken to mean that Jesus is not to be understood as a particular case of humanity in general but rather from the perspective of the Old Testament history of promise and in conflict with it. Jesus is not understood as a *theios aner* (divine man) who descended from heaven and whose life on earth is only a temporary episode. On the contrary, Jesus' life, work, death, and resurrection have utmost significance and are described in the categories of expectation appropriate to the God of promise.

The Old Testament history of promise does not simply find its fulfilment in the gospel, but it

finds its future in the gospel. Because the gospel is promise, it is a guarantee of the promised future. Here, the centrality of Christ's resurrection for the Christian faith becomes evident. The resurrection of Christ is a "history-making event" from which all other history is enlightened, questioned, and transformed (Moltmann 1967, p. 180). Pannenberg claims that in the resurrection of Christ, the end of history has occurred in proleptic anticipation. This means that what had been anticipated as the end and fulfilment of history, the resurrection of the dead, in fact happened in a proleptic way in and with Jesus. At the end of the world, there will only occur on a cosmic scale what happened in and with Jesus on an individual scale. According to Moltmann, the stories of the resurrection stand in the line of prophetic and apocalyptic expectations, hopes, and questions about what is bound to come according to the promises of God. Cross and resurrection point toward the future in promising the righteousness of God, the new life as a result of the resurrection from the dead, and the kingdom of God "in a new totality of being" (Moltmann 1967, p. 203).

Moltmann understands the Easter experiences as call appearances in which recognition of Christ coincides with the recognition of his mission and his future. He concludes that for theology, the reality of the world becomes historic in that its mission to the world is seen to be the field of the missionary charge and is examined in a search for real possibilities for the world-transforming missionary hope. Moltmann claims that "the call to obedient moulding of the world would have no object, if this world were immutable" (1967, p. 288). The world must be open to the future for good or ill. Secularization has realized these Christian expectations in the field of world history and has outstripped the Christian hope in a ► [chilastic](#) way. Thus, we cannot reject the evolutionary progressiveness of the modern age; we must incorporate the open horizon of modern history into the true eschatological horizon of the resurrection and thereby disclose to modern history its true historic character. The church cannot confine itself to serving individuals and acting as a conservative force, as society

might expect it to. The task and the mission of the church is determined by its own peculiar horizon – the eschatological expectation of the coming kingdom of God, the coming righteousness and the coming peace, and the coming freedom and dignity of all humanity. This means, according to Moltmann, "the realization of the eschatological *hope of justice*, the *humanizing* of man, the *socializing* of humanity, *peace* for all creation" (1967, p. 329).

Relevance to Science and Religion

Jürgen Moltmann as the progenitor of the theology of hope was not interested in the science and religion dialogue since his main interest was not nature but history. Moreover, his philosophical roots were in Hegelian progressive dialectic and in Ernst Bloch's neo-Marxist analysis of history and society as put forth especially in Bloch's magnum opus *The Principle of Hope*. Relevant for the science religion dialogue, however, is one aspect of the theology of hope which Moltmann put forth against Marxist varieties of hope: "All utopias of the kingdom of God or of man, all hopeful pictures of the happy life, all revolutions of the future, remain hanging in thin air and bear within them the germ of boredom and decay – and for that reason also adopt a militant and extortionate attitude toward life – as long as there is no certainty in face of death and no hope which carries love beyond death."

The physicist Frank J. Tipler vigorously, albeit quite speculatively, addressed the question of life beyond death in his book *The Physics of Immortality*. Tipler asserts that "theology is a branch of physics, that physicists can infer by calculation the existence of God and the likelihood of the resurrection of the dead to eternal life in exactly the same way as physicists calculate the properties of the electron" (1994, p. ix). He also assumes that all forms of life, including human life, are subject to the same physical laws as electrons and atoms. A human being is nothing "but a particular type of machine," the human brain only "an information processing device," and the human soul

“a program run on a computer called the brain” (1994, p. xi). Tipler wants to describe in this book the omega point theory, which he calls a testable physical theory entailing that one day in the distant future an all-present, all-knowing, and all-powerful God will resurrect each of us to an eternal life which in all its essential features will correspond to the Judeo-Christian heaven. This God will exist primarily at the end of time.

Tipler knows that the future course of the universe is such that life as an information process cannot continue forever in its present form, that is, as a carbon-based organism. If life as an information process that can sustain communication is to continue at all, it must continue to exist on some other basis. Tipler is convinced that in the not too distant future computers will possess the capability for autonomous information processing and communication and finally will even be able to reproduce themselves. Since Tipler understands a person as an entity capable of autonomous information processing and communication, and since computers will be able to assume these functions, he sees the only possibility of future “life” on the basis of computers.

On this premise, the physical mechanism of the individual resurrection is the emulation of all persons who have long since died, including their worlds, in computers of the distant future. The dead will be resurrected as soon as the capacity of all computers in the universe is so large that the capacity required for the storage of all possible human simulations is only an insignificant fraction of the total capacity. Tipler sums up his argument: “The Omega Point-Theory is the first physical resurrection theory to be fully consistent which totally agrees with the Christian resurrection theory. It is also the first redemption theory justified by reason, not by faith” (1994, p. 247). Pannenberg pointed out that “Tipler’s exposition of a future resurrection of the dead is particularly worthy of note in a time when the Christian expectations concerning the future are most often judged to be irreconcilable with the modern scientific worldview” (Pannenberg 1995, p. 477–78). Yet others accused Tipler of advancing physical reductionism because he reduces

human beings to information-processing entities. Yet his position showed that a theology of hope can also be relevant to the science and religion dialogue.

Sources of Authority

God’s word and actions understood as reflected upon in Scripture are the sources for the theology of hope. In his widely discussed “Dogmatic Theses on the Doctrine of Revelation” (1961), Pannenberg claims that God’s self-disclosure, as reflected in the biblical documents, does not occur in a direct way as a theophany but indirectly through God’s acts in history. Furthermore, Pannenberg observes that “revelation is not comprehended completely in the beginning, but at the end of the revealing history” (1968b, p. 131). History discloses its full meaning as God’s history only at the end. This is due to the fact that the individual historical acts are transparent for God not in themselves but only if perceived in the universal historical context. This can be seen especially well in the Old Testament when, in the course of history, the content of revelation ascribed to various historical events had to be developed and expanded according to the historical progression.

Pannenberg rejects a historical relativism that might result from the simple progression of history and the necessary revisions of our perception of God’s self-disclosure derived from history claiming that the universal revelation of the deity of God is not yet realized in the history of Israel but first in the destiny of Jesus of Nazareth insofar as in him the end of history has occurred in proleptic anticipation. What had been anticipated as the end and fulfilment of history, the resurrection of the dead, in fact *happened* in a proleptic way in and with Jesus.

One might question why Pannenberg attributes so much significance to the resurrection of Jesus since up to now it has been an exceptional event without any precedent or consequence in other resurrections. Pannenberg responds that one must perceive it in its proper context, the time of ► [apocalyptic](#) and the

expectation of the resurrection of the dead prevalent during that time. If we consider Jesus' resurrection in the apocalyptic context in which Jesus lived, it becomes clear that the resurrection must bear the significance of foreshadowing the eschaton. It is, on the one hand, the validation of the claim Jesus is understood to have made before Easter that he represents and carries the authority of God. But it also means that in his destiny, the end has started and God is revealed in him. Jesus therefore becomes the focal point for our understanding of eschatology. He is the paradigm and the anticipation of our own future and at the same time the inspiration and possibility of living toward that future.

Yet how much credibility does the statement carry that Jesus was resurrected? In his first major work, *Jesus – God and Man*, Pannenberg claimed that the resurrection of Jesus “is a historical event” (1968a, p. 97). The reason for this claim is that the origin of early Christianity can be properly explained only in the light of the eschatological hope in the resurrection from the dead based on the appearances of the resurrected one. For Pannenberg, Christ's resurrection is not a faith statement but one based on historical research insofar as historical research can ascertain the truthfulness of events like those involving resurrection.

Ethical Principles

The events from which the theology of hope draws its inferences are events within the universal historical horizon of humanity. Especially Wolfhart Pannenberg argued that the distinction between a special salvation history and the rest of history is obsolete. “God's redemptive deed took place within the universal correlative connections of human history and not in a ghetto of redemptive history” (1970, vol. 1, p. 41–42). Consequently, Pannenberg affirms: “In contradistinction to special appearances of the Godhead, revelation in history is open to everyone. It has universal character” (1968b, p. 135). The material with which the theology of hope deals and the conclusions it draws from them

are accessible to everyone. The peculiar ethical emphasis of the theology of hope is that the hope for eschatological completion allows and engenders a present lifestyle congruent with the expected completion.

Key Values

The theology of hope brought eschatology from the theological periphery back to the center stage of theological reflection. Moltmann claimed that Christianity in its totality is eschatological. Moreover, through the emphasis on proleptic anticipation of the goal of history, theology of hope made eschatology relevant for present-day life. Moltmann and Pannenberg made clear that eschatology is not some pipe dream about something that might occur somewhere in the distant future but that in the Christ event, the end had already occurred in a proleptic way without nullifying the hoped for universal completion. In discerning the newness of the Christ event, that is, Christ's resurrection, we can inaugurate something of this in the present. In his later book, *The Coming of God*, Moltmann still insists that Christian eschatology is not about apocalyptic final solutions because its subject is not the end at all. “On the contrary, what it is about is the new creation of all things” (1996, p. xi). Eschatology does not focus on some kind of cataclysm but again on hope, hope for eternal life, for the kingdom of God, for a new heaven and a new earth, and for the glory of God and what this hope effects. The eschatological goal is the cosmic indwelling of God in his creation. Therefore, Moltmann puts forward “Advent as eschatological category, and the category *Novum* as its historical reverse side” (1996, p. 6). This means that the emphasis is not on what is going to happen somewhere in the future, but the decisive facet is God's coming and his arrival. God's future coming enables a new human becoming. The arriving kingdom of God makes possible the conversion to this future. We notice here a summons to action yet a summons contingent on God's initiative. It comes as no surprise that this theology of hope not only instilled hope in Christian believers

but also proved fertile for further theological reflection. Therefore, Latin American *theology of liberation*, *feminist theology*, and *black theology* is directly or indirectly related to and influenced by the theology of hope.

Conceptualization

Nature/World?

The world including nature is seen as God's creation which is subjected to finitude, decay, and death. Especially in living beings, one can discern a yearning to be freed from the bondage to decay. Theology of hope affirms that there will be a new creation which entails a total transformation of this world. As Pierre Teilhard de Chardin contends: The whole evolutionary process is directed toward and finds its fulfilment in the parousia (advent) of Christ, in the creation of a new heaven and a new earth.

Human Being

A human being is seen as part of the world and therefore subjected to the same conditions as the world. The hope which is set forth for the world is also given to humans. Moreover, since as Christians they know about the new world to come, this hope incites them to inaugurate already now something of that hope. They are encouraged not to let things go their usual ways but to strive for a new world and a new liberated social arrangement though mindful that the new world to come is not a human achievement but a divine gift.

Life and Death

Life is not a human possession but a divine gift. Because of the fallen character of creation, life is bounded by death. Since the resurrection of Jesus Christ death is no longer the inevitable boundary. There is the prospect and promise of new everlasting life beyond death.

Reality

Reality is not just that which is located within our space-time continuum. Since God is not a phenomenon of space and time but the creator of that which is expressed by these categories,

God is a reality both in and beyond space and time. As Pannenberg affirmed, God is the all-determining reality. The theology of hope insists that reality transcends all possible rearrangements of our space-time continuum. This includes the hope for a totally new creation. The basis for talking about this as reality, and not as a projection of the human mind, is seen in the resurrection event. There, the possibilities of this world were transcended through the dawning of a new reality.

Knowledge

Knowledge is gained through the study of reality. Since history is continuously progressing and new insights are gained, all knowledge whether in the natural sciences or in the humanities is provisional. It can be superseded by new insights, and it must wait for its eschatological verification at the end of time.

Truth

For humans, full truth is unattainable. As the Apostle Paul asserted: "For now we see in a mirror dimly, but then we will see face to face" (1 Cor 13:12). The attainment of full truth is an eschatological promise to be fulfilled when we will see God, the all-determining reality, face to face. This eschatological proviso holds for all facets of truth both religious and nonreligious.

Perception

The perception of reality is restrained by the eschatological proviso (see: truth). It is restricted further by the respective socio-geographic stance of the one who is engaged with the theology of hope. For instance, someone in Latin America will perceive reality different from one who is engaged with it in Western Europe. Even the social analysis constitutive of perceiving the present reality will yield different results depending of the social locus of the one who conducts and applies this analysis. Since the theology of hope is not only focused on the reality of this world but perceives it in the wider horizon of God's eschatological promise, the varying perceptions are relativized or rather brought and bound together

by the common hope of the new world to come and its proleptic anticipation in the present.

Time

Time is one of the important categories of the theology of hope. Time is not circular and repetitive but linear. Since time is fleeting, it shows the transitoriness of the present age. At the same time, it beckons us to the future, a future enabled by God's redemptive activity. Time is not a never-ending configuration but will find its completion in God's eternity. The so-called last day "is at the same time the beginning of eternity: a beginning without end. That is the 'fulfilled time', the aeonic time, the time filled with eternity, the eternal time," says Moltmann in *The Coming of God* (p. 295).

Consciousness

Especially Paulo Freire in his classic *Pedagogy of the Oppressed* emphasized consciousness, raising as an important facet of liberation theology. The oppressed people must first perceive the actual situation in which they live in order to evaluate steps and possibilities in which direction they could change that situation. The actual consciousness then leads to potential consciousness.

Rationality/Reason

Reason is the primary mental tool with which the investigation of the present reality is conducted and with which the future hope is elucidated on the basis of this reality. Faith does not replace reason, but it is the trust that the one, that is, God, who has proven to be trustworthy in the past, will also be trustworthy in the future.

Mystery

Mystery is a term which is not used in the theology of hope. The only mystery, meaning something unexplainable, would be the reason why God has always been faithful to humanity regardless of its alienation from God, with God demarking a history of promise including the promise of a totally new creation including a redeemed humanity.

Relevant Themes

Since the theology of hope is fundamentally concerned about the future and the present arrangement of creation, ecological issues cannot be avoided. Liberation does not just pertain to humanity but to all created beings. Creation or nature is not viewed as something static but as a dynamic arrangement projecting itself toward the future. One can even speak of a historization of the cosmos. A strictly naturalistic interpretation of the cosmos is no longer possible.
